

- The mandible rotates upward-forward during intrusion of the mx posterior teeth:
  - By adjusting the point of attachment of the spring to the plate, a cl.II or cl.III component can be added to the force.
  - May use cl.II or III elastics for compensation.
  - Eruption of the lower molars must be controlled, if a reduction of the anterior face height is the goal. Avoid relapse of the anterior open bite.

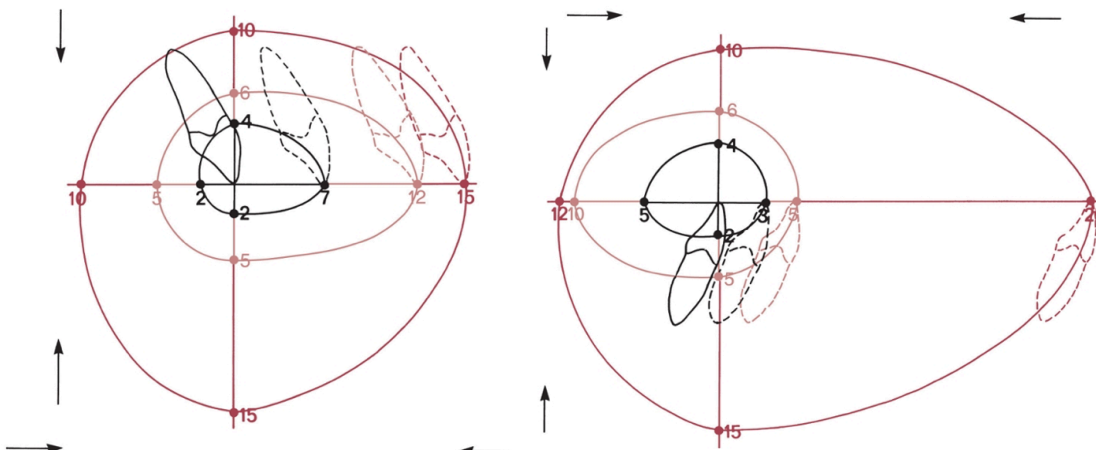

- Maximum force =  $\leq 200$  mg to a posterior segment of 3 teeth.
- Intrusion = Slower than other tooth movements. Maximum 0.5 mm / m.
- **0.5 mm posterior intrusion = 1 mm closure of anterior open bite.**
- **Maximum intrusion: ~ 4 mm. 15-20% lost in short term.**
- Eruption of the incisors can compensate for relapse of the mx molar intrusion, unexpected late downward growth of the mx or elongation of mn molars.
- No studies about long term stability are available at the moment.
- Scheffler, 2014: Intrusion of mx posterior teeth with skeletal anchorage
  - Mx molar intrusion can give satisfactory correction of moderately severe open bites: up to 6 mm in the long term from intrusion, more with extrusion of incisors.
  - Lower molar eruption must be controlled to gain a skeletal change with mx molar intrusion.
  - Clinical experience suggests that intrusion of both mx and mn posterior teeth can allow closure of more severe open bites.
  - Eruption of mx and/or mn incisors partially compensates for re-rotation of the mn, so bite opening after open bite correction rarely occurs.
  - Le Fort 1 surgery to superiorly reposition the mx is more likely to produce a significant shortening of anterior face height.

7. Intrusion of mandibular posterior teeth	<ul style="list-style-type: none"> <li>- Bone screw between the molar and premolar roots.</li> <li>- NiTi coil springs for intrusion.</li> <li>- Wires to transfer force to the 2<sup>nd</sup> molars and 2<sup>nd</sup> premolars soldered to bands 6-6</li> <li>- Adjustable lingual arch.</li> </ul>

	<ul style="list-style-type: none"> <li>- Spurs attached to the lingual arch to create tongue repositioning away from the open bite.</li> </ul> <div data-bbox="507 275 1291 920">  </div>
<b>Finishing and retention</b>	<ul style="list-style-type: none"> <li>- Positioners: <ul style="list-style-type: none"> <li>• Rarely indicated for adult patients.</li> <li>• Never use in patients with severe periodontal bone loss.</li> </ul> </li> <li>- <u>Mobile teeth with severe bone loss:</u> Splinting.</li> <li>- <u>Molar intrusion:</u> Use retainers with posterior bite blocks.</li> </ul>

## Proffit Chapter 20:

### Combined Surgical and Orthodontic Treatment

Indications for surgery	<ul style="list-style-type: none"> <li>- Orthodontic problems that are so severe that neither growth modification nor camouflage can help.</li> <li>- Surgery is not a substitute for orthodontics.</li> </ul>
Development of surgery	<ul style="list-style-type: none"> <li>- <b>Early 20<sup>th</sup> century</b>: Begin of body osteotomies for prognathism.</li> <li>- <b>1957</b>: Sagittal split ramus osteotomy with IO approach: <ul style="list-style-type: none"> <li>o = Begin of the modern surgery.</li> <li>o Possibility to lengthen or shorten the mandible.</li> </ul> </li> <li>- <b>1960</b>: Improvement of mx surgery → Le Fort 1.</li> <li>- <b>1980s</b>: Movements of both jaws, the chin and the dentoalveolar segments possible.</li> <li>- <b>1990</b>: Rigid internal fixation.</li> <li>- <b>21<sup>st</sup> century</b>: Facial distraction osteogenesis.</li> </ul>
<b>The borderline patient: Camouflage vs. surgery</b>	
Influencing factors	<ul style="list-style-type: none"> <li>- Required tooth movement.</li> <li>- Patients age → growth modification possible?</li> <li>- Soft tissue limitations.</li> <li>- Facial appearance is more important than anchorage.</li> <li>- Soft tissue limitations often are a major factor in the decision for surgical or orthodontic tx.</li> </ul>
Envelope of discrepancy	<ul style="list-style-type: none"> <li>- Outlines the limits of hard tissue change towards ideal occlusion: <ol style="list-style-type: none"> <li>1. Orthodontic tooth movement alone</li> <li>2. Orthodontic tooth movement + growth modification</li> <li>3. Orthognathic surgery</li> </ol> </li> <li>- Potential for tooth movement: <ul style="list-style-type: none"> <li>• Forward &gt; backward</li> <li>• Extrusion &gt; intrusion</li> <li>• Growth modification always includes both jaws → Same envelope.</li> </ul> </li> </ul>
	
Orthognathic surgery versus temporary skeletal anchorage	<ul style="list-style-type: none"> <li>- The limits of orthodontic tx are much more a matter of facial appearance than anchorage.</li> <li>- Intrusion of posterior mx teeth is a good alternative to moving the mx up with a Le Fort 1 osteotomy (<i>Scheffler, 2014</i>).</li> <li>- Anterior open bite &gt; -6 mm → surgery or intrusion of mx and mn posterior teeth.</li> <li>- Protraction of the maxilla with cl.III elastics to skeletal anchorage is a good substitute for surgery if the mx deficit is not too severe. (<i>De Clerck 2010 &amp; 2012</i>)</li> </ul>
Esthetic and psychosocial considerations	<ul style="list-style-type: none"> <li>• If esthetic is a major goal, changes of the nose or the soft tissues (plastic surgery) are may be necessary in addition to the jaw surgery.</li> <li>• <u>Older people</u>: Difficulty to adapt to significant changes in facial appearance. Minimize changes if possible.</li> <li>• <u>Younger people</u>: Wish to change in appearance with orthognathic surgery.</li> </ul>
