

Red = Angles line of occlusion

- Mx: Central fossa of the molars, cingulum of the canines & incisors.
- Mn: Buccal cusps of the molars, incisal edges of the canines & incisors.

Green = Esthetic line

- 3 rotational axes pitch perpendicular to a plane:
 - **Pitch axis:** (dt. Querachse) Up-down deviations around the anteroposterior axis.
(vertical relation of the teeth to the lips and cheeks)
 - **Roll-axis:** (dt. Längsachse) Up-down deviations around the transverse axis.
vertical position of the teeth when there is a difference between the left and right side)
 - **Yaw-axis:** (dt. Hochachse) Left-right deviations around the vertical axis.
(midlines deviations /chin asymmetry)
Rare in the maxilla, present in 40% patients with deficient or excessive mn growth.

| | |
|---|---|
| Classification by the characteristics of malocclusion | <ol style="list-style-type: none"> 1. Evaluation of facial proportions and esthetics. 2. Evaluation of the alignment and symmetry within the arches. 3. Evaluation of the transverse plane of space: <ul style="list-style-type: none"> ○ Dental or skeletal malocclusion? → Width of the skeletal base can be seen by the width of the palatal vault on casts. ○ Maxillary lingual crossbite / mandibular buccal crossbite (rare)? ○ Transverse displacements of the lower molars in the mandible are rare → it means, in most cases the maxilla is not correct. ○ Specify which jaw is not correct. 4. Evaluation of the anteroposterior plane of space. 5. Evaluation of the vertical plane of space: Why? → Cause? What anatomic location is the discrepancy? |
|---|---|

Development of a problem list

2 types of problems:

1. Those relating to disease or pathologic processes.
 2. Those relating to disturbance of development which have created the patient's malocclusion.
→ = Orthodontic problem list.
- If possible, problems should be indicated quantitatively or at least classified as mild, moderate or severe.
 - All problems must be identified and characterized, omitting nothing of significance.

Proffit Chapter 7:

Orthodontic Treatment Planning: From the Problem List to a Specific Plan

| Treatment planning concepts and goals | |
|---------------------------------------|--|
| Treatment plan | <ul style="list-style-type: none">- = Strategy that comes from a wise clinician using his best judgment to address the problem and maximizing benefit to the patient while minimizing costs and risks.- Should always be developed with the patient.- Cost-benefit / risk-benefit analysis.- Avoid missed opportunities (false negative tx) or excessive tx (false positive). |
| Major issues in planning tx | |
| Patient input | <p>Patient must be involved in tx planning:</p> <ul style="list-style-type: none">• Ethically: Patient has a right to control what happens.• Practically: Better compliance for a tx that the patient supports. |
| Predictability and complexity of tx | <ul style="list-style-type: none">- Tx choice must be evidence based.- Complexity of tx defines who should do it → generalist vs. specialist. |

Dental crowding: To expand or extract

| | Extraction | Expansion |
|--|--|---|
| Esthetic considerations | | |
| Lips | <ul style="list-style-type: none"> - The relative prominence is affected by the nose and the chin. - Lower lips should be at least as prominent as the chin. - Follow $\frac{2}{3}$ the extent of the incisor movement | <ul style="list-style-type: none"> - Flat lips. - Risk of retrusive upper lip in case of excessive incisor retraction. - Full lips - Teeth more prominent: → Cave insufficient lip closure at rest. - Thin lips follow the tooth movement more than thick lips. |
| Stability Considerations | | |
| Maximum expansion mandible | | <p>- More stable</p> <p>Mandibula = Limitation for a stable expansion.</p> <ul style="list-style-type: none"> - Maximum 2 mm forward movement limited by lip pressure. (pressure increases sharply after this point) - Lingually tipped incisors can be further moved forward. - Severely crowded incisors are maybe already protruded and no additional extra protrusion is allowed. Cave: Risk of fenestration of the alveolar bone or gingival recessions. - Expansion around the canines is not stable. (intercanine width diminishes with age even in untreated individual) - Expansion regio premolars and molars can be stable if not overdone. - Increased risk of fenestration beyond 3 mm of transverse tooth movement. <p>- Maxilla: Expansion posterior 3+3 possible by opening the midpalatal suture</p> |
| <ul style="list-style-type: none"> - The more you can expand without moving the incisors forward, the more patients you can treat without extractions. - The more you can close extraction spaces without overretracting the incisors, the more you can treat with extractions. - The lower arch is more constrained than the upper: → Limitations for stable expansion are tighter than in the upper arch. - Excessive expansion increases the risk of mucogingival problems. - Extraction or expansion make no difference for masticatory function. - Lip moves usually $\frac{2}{3}$ of the distance that the incisors are retracted. Lip retraction stops when the protruding lips come into contact at rest. → Maximum 2-3 mm lip retraction in cl.I extraction cases - Lip pressure is one of the limiting factors in forward movement of the incisors: Lip pressure increases sharply 2 mm out into space usually occupied by the lips. - Patients with similar malocclusions treated either with or without extractions show little or no difference in profile and frontal appearance. | | |
| < 4 mm arch length discrepancy | <ul style="list-style-type: none"> - Extractions are rarely indicated. - May just slightly reduce the width of selected teeth without expansion. | |
| 5-9 mm arch length discrepancy | <ul style="list-style-type: none"> - Extraction and non-extraction tx possible depending on hard- and soft tissue characteristics. - Several different teeth can be chosen if extractions are planned. - Without extractions, there's normally expansion necessary. | |
| ≥ 10 mm arch length discrepancy | <ul style="list-style-type: none"> - Extractions are almost always indicated. - Little or no effect on lip support and facial appearance, if the crowding is so severe. - Choice 4±4 or 4+4 & 2-2 for extraction. | |

Spaces in mm from various extractions: (note clear in Proffit if the values are for the mn or the mx)
 (with typical anchorage management, not skeletal anchorage)

| Extraction | Relief of incisors crowding | Incisor retraction | | Posterior forward | |
|------------------------|-----------------------------------|--------------------|---------|-------------------|---------|
| | | Maximum | Minimum | Maximum | Minimum |
| Central incisor | 5 | 3 | 2 | 1 | 0 |
| Lateral | 5 | 3 | 2 | 1 | 0 |
| Canine | 6 | 5 | 3 | 2 | 0 |
| First premolar | 5 | 5 | 2 | 5 | 2 |
| Second premolar | 3 | 3 | 0 | 6 | 4 |
| First molar | 3 | 2 | 0 | 8 | 6 |
| Second molar | 2 | 1 | 0 | - | - |

| Planning treatment for maximal esthetic improvement | |
|---|--|
| Macro-esthetics: Facial disproportions | <p>Camouflage:</p> <ul style="list-style-type: none"> - Camouflage = Correct facial disproportions without changing the jaws position. - Success lies in the eye of the beholder. → For borderline cases, the dentist cannot judge if camouflage tx is successful, but only the patient / family / friends. - Depends on the patient, if facial appearance is satisfactory enough with camouflage or if a greater change with surgery is needed. - More possibilities to treat cl.II cases than cl.III cases. <p>Surgery:</p> <ul style="list-style-type: none"> - Pictures with simulation of different tx options are appreciated by patients. → Aesthetic awareness↑, but not creation of unrealistic expectations. - Mx or mx advancement increases the volume and makes patients look younger / The contrary is also true for mx or mn posterior reposition. - Genioplasty: <ul style="list-style-type: none"> o Improves lower incisors stability and decreases the chance of gingival recession by adding bone in the front of protruding incisors. o Enhances facial appearance - Sometimes cosmetic plastic surgery is indicated: <ul style="list-style-type: none"> o Rhinoplasty: Indicated for nose deviations, dorsal humps... o Correction of paranasal deficiencies with grafts / alloplastic implants. <p>Growth modification:</p> <ul style="list-style-type: none"> - Greater growth modification possible for cl.III than cl.II cases. (Reverse than for camouflage tx) - Computer predictions of growing patients are often inaccurate, because of the difficulty of predicting growth. |
| Mini-esthetics: Improving the smile framework | <ul style="list-style-type: none"> - Vertical tooth-lip relation: <ul style="list-style-type: none"> o Minimum 75% of the crown visible. o Tooth display female > male. o Elongation of upper incisors makes the patient look younger. o Extrusive / intrusive mechanics with archwires. o Absolut intrusion o Relative intrusion: <ul style="list-style-type: none"> ▪ Incisor eruption is prevented while growth provides vertical space into which the posterior teeth erupt. o Extrusion: <ul style="list-style-type: none"> ▪ Elongation of posterior teeth which causes the jaws to rotate. ▪ Increase of anterior face height. o Use of class II elastics → Tendency to rotate the occlusal plan down anteriorly. o Orthognathic surgery. o Recontouring the gingiva to gain normal crown height. - Buccal corridors: <ul style="list-style-type: none"> o Small corridors are preferred (16%). o Transversal mx expansion decreases buccal corridor width and improves the appearance of the smile. o Too much expansion of the natural dentition can have an unnatural appearance of the teeth. - Smile arc: <ul style="list-style-type: none"> o Most important determinant of the attractiveness of the smile. o Should follow the contour of the lower lip. o Is determined by placing the brackets / step bends. - Smile symmetry <ul style="list-style-type: none"> • Greater elevation of the lip on one side, which pretends teeth asymmetry is not possible to correct with tx. |
| Micro-esthetics: Enhance the appearance of the teeth | <ul style="list-style-type: none"> - Reshape teeth: <ul style="list-style-type: none"> • Reshape incisal edges of anterior teeth, remove mamelons, smooth out irregular edges from minor traumas. • Maybe easier to be done before brackets are placed. • Needed primarily when one tooth is used as a substitute for another (3→2). |

| | |
|--|--|
| | <ul style="list-style-type: none"> - Correcting black triangles: <ul style="list-style-type: none"> • Remove enamel at the contact points so that the teeth can be moved closer together. → Moving the contact area apically eliminates most of the space. • Do not distort the proportional relationship of the teeth to each other. • Progression of connector heights should be maintained. → May also correct 32+23 if 1+1 are corrected (i.e. narrowed). - Interact with a restorative dentist: composite build-ups, ceramic laminates <ul style="list-style-type: none"> • Laminates are indicated if the tooth's color and shade should be changed in addition to the size of the crown. • Timing: <ul style="list-style-type: none"> ○ At the end of tx: Vacuum formed retainer to hold the teeth, new retainer after the restorations are done. <i>or</i> ○ Short before the end of tx: Leave some extra space, remove brackets, replace brackets immediate after the restorations are done and close the remaining space. - Reshape gingival contours: Application of soft laser: <ul style="list-style-type: none"> • Does not cut hard tissues → no risk of damage to the teeth or alveolar bone. • Biologic dressing: Coagulates, sterilizes and seals the soft tissues. • No bleeding. • No waiting period for healing. |
|--|--|

| Planning comprehensive orthodontic tx | |
|--|---|
| | <ol style="list-style-type: none"> 1. Pathologic processes must be under control: They are not more important than orthodontic development problems, but could become accentuated by orthodontic tx. 2. Setting priorities to the orthodontic problems in a problem list: Tx plan must focus on what's most important for the patient. Informed consent is necessary if the dentist and a patient do not agree on what's the most important issue. 3. Find a solution for each problem as if it was the only one: Broad possibilities, no details of tx procedure are required. 4. Interactions between possible solutions. 5. Compromise: Sometimes one tx plan will not solve all the problems for the patient. → Emphasize one of the goals (should be the patient's most important) at the expense of the others. 6. Analysis of benefit vs. costs: "Is it worth?" Costs = Burden of tx: money, discomfort, aggravation, time, cooperation... 7. Other considerations: Uncertainty of growth pattern... <p>- Periodontal disease:</p> <ul style="list-style-type: none"> • Orthodontic tx in the presence of active periodontal disease is likely to accelerate the disease process. (<i>Thilander, 1996</i>) • In the absence of active disease orthodontic tx will not lead to further bone loss, even if significant bone loss has occurred previously. (<i>Ogihara, 2010</i>) |
| Patient-parent consultation: Obtaining informed consent | <ul style="list-style-type: none"> - No paternalistic approach (doctor knows what's best and takes the decisions). - Oral information required. Handouts, videos... are not enough): <ul style="list-style-type: none"> • Existing problems. • Tx and tx alternatives. • Interactions, unavoidable compromises, practical considerations. • Possible outcomes. - Inform about side effects: <ul style="list-style-type: none"> • Pain and discomfort. • Root resorptions. • Possible damage to the teeth caused by inadequate hygiene: White spots, caries, gingivitis. • Issues unique to the patient: Missing / impacted teeth, TMJ... - Patients remember information best when it is given in layman's terminology and by using visual presentation. - Interactions, unavoidable compromises and practical considerations must be shared with the patient. - Involve the patient in the final decision: → Putting the problem on him and giving him responsibility makes him more cooperative. |
| Detailed plan: Specifying the tx procedures | <ul style="list-style-type: none"> - Any tx procedure must fulfill two criteria: <ul style="list-style-type: none"> • Effectiveness in producing the desired result. • Efficiency in doing so without wasting either doctor's or patient's time. → Must be considered for the various tx possibilities. |

| Treatment planning in special circumstances | |
|---|--|
| Dental disease problems | <ul style="list-style-type: none"> - Root filled teeth: <ul style="list-style-type: none"> o Move like normal teeth as long as the periodontal ligament is normal. o No greater risk for root resorption. - Trauma teeth: Higher risk of root resorption in case of a severe trauma. - Periodontics: <ul style="list-style-type: none"> o Prior periodontal tx is no contraindication for orthodontic tx. → Exception: Osseous surgery. o Consider a graft prior to orthodontics in case of a small attached gingiva in the mandibular anterior region. → There is mixed evidence regarding the usefulness of pre-tx and post-tx gingival grafting. |
| Systemic disease problems | <ul style="list-style-type: none"> - Patient with other diseases present a greater risk for compliance. - Avoid prolonged comprehensive orthodontic tx, accept compromises. - <u>Diabetes</u>: <ul style="list-style-type: none"> o Risk of accelerated periodontal breakdown if not under control. o No problems if under control. - <u>Arthritic degeneration</u>: <ul style="list-style-type: none"> • Juvenile rheumatoid arthritis can produce severe mn deficiency. • Adult rheumatoid arthritis can destroy the condylar process and create deformity. • Long term steroid medicaments can increase periodontal problems. • Bisphosphonates can make orthodontic tx almost impossible. - <u>Pregnancy</u>: <ul style="list-style-type: none"> • Orthodontic tx is possible but don't start during pregnancy. • No x-rays. • Gingival hyperplasia due to hormonal variations. • Bone turnover makes patients susceptible for alveolar bone loss and root resorptions. • Apply a holding pattern in the last trimester. • Little jaw growth is possible during pregnancy. |
| Anomalies and jaw injuries | <ul style="list-style-type: none"> - <u>Fractures of the maxilla</u>: <ul style="list-style-type: none"> • Rare. • Immediate reposition is indicated. If not possible, apply protraction force from a face mask before the fractures heal completely for repositioning. - <u>Asymmetric mandibular deficiency</u>: <ul style="list-style-type: none"> • If the translation of the condyle is restricted due to scarring, don't use a functional appliance before surgical correction. • Indicated appliance: <ul style="list-style-type: none"> o Bite block between the teeth on the normal side while providing space for eruption on the deficient side. o More advancement on the deficient side in the construction bite. - <u>Hemimandibular hypertrophy</u>: 2 surgical tx possibilities: <ul style="list-style-type: none"> • Ramus osteotomy to correct the asymmetry after the excessive growth has ceased. (preferred if possible) • Condylectomy to remove the excessively growing condyle + joint reconstruction. Cave: Try to avoid TMJ surgery → risk for scar tissue formation. - <u>Sleep apnoe</u>: <ul style="list-style-type: none"> • Origin: Blockage or severe narrowing of the airways at any point between the nostrils and lung, but usually in the upper pharynx to midpharynx (blocked by the tongue when muscles relax during sleep and the mn drops backward). • Airway width cannot be evaluated in lateral ceph and only limited in 3D imaging. (instant changes all the time) • Risk factors: <ul style="list-style-type: none"> o Mn deficiency. o Obesity. |

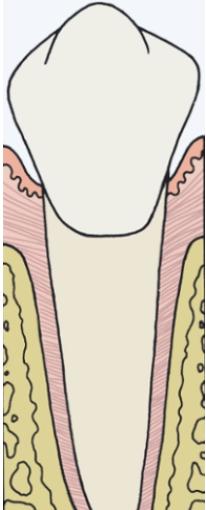

| | | | | | | | | | | | | | |
|----------------------|---|-----------|-----------------------------------|--------------|----------------|-----------|---------------------------------|-----------|--|-------------|--|------------------|-----------------------|
| | <ul style="list-style-type: none"> ○ Increasing Age. ○ Alcohol. ● Tx: <ul style="list-style-type: none"> ○ An IO appliance to hold the mn forward can be effective for patients with low to moderate sleep apnoe severity. ○ Surgical mn advancement. <i>(SKG Bern: only effective if minimum 6-7 mm advancement)</i> ○ Widening of the mx: → Effective only if the obstruction is within the nasal part. ○ Surgical mx upward reposition can decrease resistance to nasal airflow. (nostrils are widened) | | | | | | | | | | | | |
| Cleft lip and palate | <table border="1" style="width: 100%; border-collapse: collapse;"> <tr> <td style="padding: 2px;">2-4 weeks</td> <td style="padding: 2px;">Lip closure (infant orthopedics?)</td> </tr> <tr> <td style="padding: 2px;">12-18 months</td> <td style="padding: 2px;">Palate closure</td> </tr> <tr> <td style="padding: 2px;">7-8 years</td> <td style="padding: 2px;">Alignment of maxillary incisors</td> </tr> <tr> <td style="padding: 2px;">7-9 years</td> <td style="padding: 2px;">Alveolar bone graft (<i>before eruption of lateral incisor, if present, or canine</i>)</td> </tr> <tr> <td style="padding: 2px;">Adolescence</td> <td style="padding: 2px;">Comprehensive orthodontics Lip/nose revision?</td> </tr> <tr> <td style="padding: 2px;">Late adolescence</td> <td style="padding: 2px;">Orthognathic surgery?</td> </tr> </table> <p>- <u>Infant orthopedics:</u></p> <ul style="list-style-type: none"> ● 2-4 weeks: Lip closure. ● Early grafting of the alveolar process is contraindicated. → Tends to interfere with later growth. ● In case of bilateral clefts, the premaxillary segment is often displaced anteriorly and the posterior maxillary segments are lingually collapsed. <ul style="list-style-type: none"> - Expand the posterior segments. - Light elastic strap across the anterior segment / Orthodontic appliance pinned to the segments which applies a contraction force / Pressure from the lips to reposition the anterior part. - Short-term benefit is more impressive than the long-term benefit. → Only indicated in bilateral clefts. - Alternative: Lip closure in two stages. <p>- <u>Late primary and early mixed dentition:</u></p> <ul style="list-style-type: none"> ● Many orthodontic problems arise from effects of the surgical repair and not because of the cleft itself. → E.g. anterior & lateral crossbite caused by strain of the repaired lip and repair of the palatal vault is not found in untreated cleft individuals. ● Correct the incisor position: Often they erupt rotated and in a crossbite. ● Prepare the patient for the alveolar bone graft: About age 7y, if 2+2 are present / before eruption of 3+3 if 2+2 are not present. ● Try to make erupting a permanent tooth through the grafted area so that the cleft is obliterated. <p>- <u>Early permanent dentition treatment:</u></p> <ul style="list-style-type: none"> ● Often correction of a posterior crossbite is necessary. ● Teeth are likely to be malaligned. ● In case of missing teeth: <ul style="list-style-type: none"> ○ Close the space. ○ Position other teeth as abutments for fixed prosthodontics. (resin-bonded bridge) ● No implants in the cleft area. <p>- <u>Orthognathic surgery for patients with CLP</u></p> <ul style="list-style-type: none"> ● Often relapse of an anterior and lateral crossbite due deficient maxillary growth. → Surgery necessary to bring the mx downward & forward + mn setback. ● Restorative work to replace missing teeth. ● Esthetic surgery / pharyngeal flaps to control the respiration are sometimes indicated. | 2-4 weeks | Lip closure (infant orthopedics?) | 12-18 months | Palate closure | 7-8 years | Alignment of maxillary incisors | 7-9 years | Alveolar bone graft (<i>before eruption of lateral incisor, if present, or canine</i>) | Adolescence | Comprehensive orthodontics Lip/nose revision? | Late adolescence | Orthognathic surgery? |
| 2-4 weeks | Lip closure (infant orthopedics?) | | | | | | | | | | | | |
| 12-18 months | Palate closure | | | | | | | | | | | | |
| 7-8 years | Alignment of maxillary incisors | | | | | | | | | | | | |

| Adolescence | Comprehensive orthodontics Lip/nose revision? | | | | | | | | | | | | |
| Late adolescence | Orthognathic surgery? | | | | | | | | | | | | |

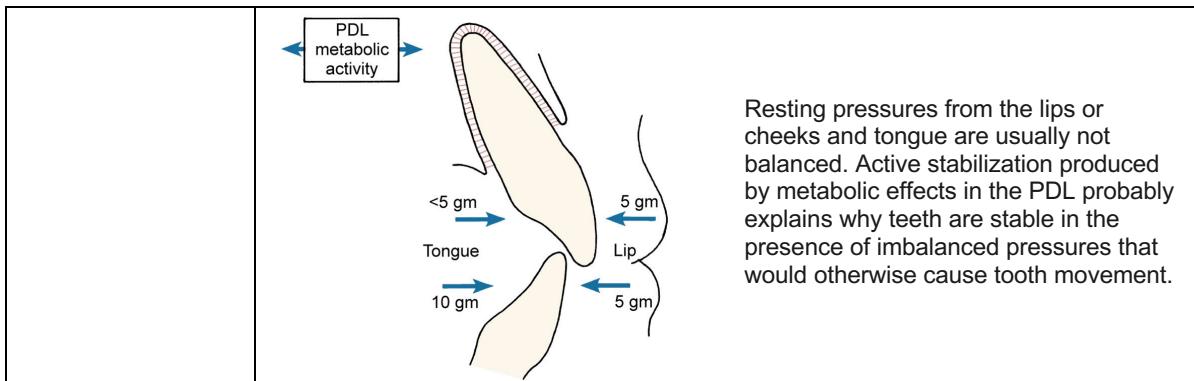

Reducing uncertainty in planning treatment

- Tx changes are only predictable in the absence of growth.
- The amount and direction of growth is difficult to predict:
 - Best done with templates that show the expected direction and increment of growth at specific points / ages or as a series of complete templates from which a change at a given point can be deducted.
(separate templates for sexes, racial groups, categories of malocclusion)
- Cave: Growth that deviated from the norm is likely to continue in a deviated way.
 - Average values are unlikely to be correct for predictions.
- Superimpose cephalograms with profile images to predict tx results.
- Therapeutic diagnosis: = Implement a conservative tx plan initially and evaluate the results after some months for the definitive planning. Tx takes a bit longer, but incorrect decisions are prevented.

Proffit Chapter 8:

Biologic Basis of Orthodontic Therapy

| <ul style="list-style-type: none"> - Biomechanics: Reaction of the dental and facial structures (biologic system) to orthodontic force (mechanics). - Tooth moves through the bone carrying its attachment apparatus with him as the socket of the tooth migrates mediated by the periodontal ligament. - Forces applied to the teeth can also affect bone apposition and resorption at sites distant from the teeth: Sutures of the maxilla, bony surfaces of the TMJ. | | | | | | | | | | | |
|--|---|----------|-------|------|--|-------|--|-------|---|------------------|---------------------------------|
| Periodontal and bone response to normal function | | | | | | | | | | | |
| Periodontal ligament structure  | <ul style="list-style-type: none"> - PDL 0.5 mm wide. - Network of parallel collagenous fibers that run at an angle: Attaching further apically on the tooth than on the adjacent alveolar bone to resist expected displacement of the tooth during normal function. - Cellular elements: <ul style="list-style-type: none"> • Undifferentiated mesenchymal cells and their progeny in form of fibroblasts (same cells can work as fibroclasts) and osteoblasts. • → Mechanical strain induces the differentiation of fibroblasts via calcitonin. • Cementoblasts • Osteoclasts and cementoclasts: Cell origin is controversial: Most are hematogenous origin, some derived from stem cells in the local area. - Blood vessels and cells from the vascular system. - Neural elements: <ul style="list-style-type: none"> • Unmyelinated free endings for the perception of pain. • Complex receptors for pressure and positional information (proprioception). - Tissue fluid: Derived from the vascular system. | | | | | | | | | | |
| Response to normal function | <ul style="list-style-type: none"> - Normal tooth contact ≤1s, 1-2 kg up to 50 kg → Normal mastication (<1 s) is possible without pain. <table border="1"> <thead> <tr> <th>Time (s)</th> <th>Event</th> </tr> </thead> <tbody> <tr> <td><1 s</td> <td>PDL fluid is incompressible. Alveolar bone bends → piezoelectric signal is generated.</td> </tr> <tr> <td>1-2 s</td> <td>PDL fluid is expressed. Tooth moves within the PDL space.</td> </tr> <tr> <td>3-5 s</td> <td>PDL fluid squeezed out. Tooth displaces within the PDL, compressing the ligament itself against the adjacent bone: → Pain if the pressure is heavy.</td> </tr> <tr> <td>Prolonged forces</td> <td>Remodeling of the adjacent bone</td> </tr> </tbody> </table> <ul style="list-style-type: none"> - Alveolar bone bends also during normal mouth opening / closing. → Distance between 6-6 decreases 2-3 mm. - Bone bending in response to normal function generates piezoelectric currents that appear to be an important stimulus to skeletal regeneration and repair. - Prolonged force (orthodontic or by soft tissue stretch) produces a different response by remodeling of the adjacent bone. | Time (s) | Event | <1 s | PDL fluid is incompressible. Alveolar bone bends → piezoelectric signal is generated. | 1-2 s | PDL fluid is expressed. Tooth moves within the PDL space. | 3-5 s | PDL fluid squeezed out. Tooth displaces within the PDL, compressing the ligament itself against the adjacent bone: → Pain if the pressure is heavy. | Prolonged forces | Remodeling of the adjacent bone |
| Time (s) | Event | | | | | | | | | | |
| <1 s | PDL fluid is incompressible. Alveolar bone bends → piezoelectric signal is generated. | | | | | | | | | | |
| 1-2 s | PDL fluid is expressed. Tooth moves within the PDL space. | | | | | | | | | | |
| 3-5 s | PDL fluid squeezed out. Tooth displaces within the PDL, compressing the ligament itself against the adjacent bone: → Pain if the pressure is heavy. | | | | | | | | | | |
| Prolonged forces | Remodeling of the adjacent bone | | | | | | | | | | |
| Periodontal ligament in eruption and stabilization of teeth | <ul style="list-style-type: none"> - PDL itself can produce tooth movement. - Adaptation to metabolic events with formation, crosslinking and maturational shortening of collagen fibers. - Ability to generate a force: → Orthodontic forces under the stabilization level are ineffective. Threshold minimum 5-10 gm/cm². | | | | | | | | | | |

Periodontal ligament and bone response to sustained force

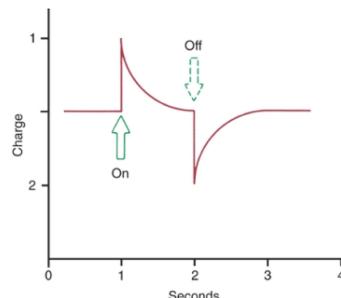

Biologic control of tooth movement:

2 theories → both may play a role, but the chemical messenger theory (pressure-tension) is dominant.

1. Biologic electricity: Piezoelectric currents

- Piezoelectric currents:

- = Deformation of a crystallin structure by external forces (bone bends) produces a flow of electric current as electrons are displaced from one location to another.
- Opposite current if the force is released.
- Quick decay rate.
- Important stimulus for skeletal regeneration / repair and adaption to the functional demand.
- Poor relation with response to orthodontic tooth movement.

Pro:

- Ions in the fluids of living bone interact with the created electric field:
→ Electric signal in form of volts & temperature changes → currents can be detected in the extracellular fluids.
- Electromagnetic fields can affect cell membrane potentials and permeability:
→ = trigger for changes in cellular activity.
- **Reverse piezoelectric effect:**
Application of an electric field can also cause crystal deformation and produce force in doing so.
- Possibility for using external electric fields in bone healing and regeneration after injury.

Contra:

- Sustained force like orthodontic force does not produce piezoelectric or other types of stress-generated signals. Nothing happens as long as the force is maintained.
- A vibrating application of pressure would be advantageous if stress-generated signals were important in producing bone remodeling.
→ Idea of vibrating devices.
Studies showed however little or no advantage in using vibration to generate piezoelectric signals versus sustained force for the movement of teeth.
- No evidence that moving teeth with magnetic force reduces pain and mobility.

2. Pressure-tension theory: Chemical messengers

- Cellular changes produced by chemical messengers create movement.
- Chemical messengers (bind to receptors) can be generated by:
 - Alterations in blood flow
 - Mechanical stress:
 - Integrins in the cell membran connect the extracellular actin with the intracellular cytoskeleton.
 - Released by damaged cells in the PDL
- Alteration in blood flow through the PDL creates changes in the chemical environment (O_2 , CO_2): → Stimulation for release of active agents.
- Mechanical effects on cells in the PDL cause release of cytokines, prostaglandins and other chemical messengers.
- Cells are activated by biologic messengers.
- Stages of tooth movement:
 1. Initial compression and blood flow alterations associated with pressure within the PDL.
 2. Formation and/or release of chemical messengers.
 3. Activation of osteoblasts and osteoclasts leading to bone remodeling.

Effect of force magnitude

TABLE 8.2 Physiologic Response to Sustained Pressure Against a Tooth

| TIME | | Event |
|----------------|----------------|--|
| Light Pressure | Heavy Pressure | |
| <1 second | | PDL fluid incompressible, alveolar bone bends, piezoelectric signal generated |
| 1-2 seconds | | PDL fluid expressed, tooth moves within PDL space |
| 3-5 seconds | | Blood vessels within PDL partially compressed on pressure side, dilated on tension side; PDL fibers and cells mechanically distorted |
| Minutes | | Blood flow altered, oxygen tension begins to change; prostaglandins and cytokines released |
| Hours | | Metabolic changes occurring: chemical messengers affect cellular activity, enzyme levels change |
| ~4 hours | | Increased cAMP levels detectable, cellular differentiation begins within PDL |
| ~2 days | | Tooth movement beginning as osteoclasts and osteoblasts remodel bony socket |
| | 3-5 seconds | Blood vessels within PDL occluded on pressure side |
| | Minutes | Blood flow cut off to compressed PDL area |
| | Hours | Cell death in compressed area |
| | 3-5 days | Cell differentiation in adjacent narrow spaces, undermining resorption begins |
| | 7-14 days | Undermining resorption removes lamina dura adjacent to compressed PDL, tooth movement occurs |

cAMP, Cyclic adenosine monophosphate; PDL, periodontal ligament.

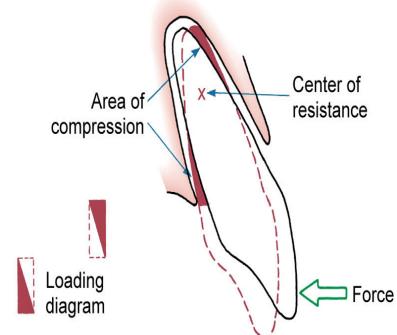

- Response to sustained force against the teeth is a function of the force magnitude.
- Force against a tooth ↑ → PDL perfusion ↓.

| | |
|---------------------|---|
| Light force: | <ul style="list-style-type: none"> - Survival of cells within the PDL - Remodeling off the tooth socket by relatively painless “frontal resorption” of the tooth socket. <ol style="list-style-type: none"> 1. Prostaglandin and Interleukin 1-beta levels (IL1β) increase within the PDL within a short time after the application of pressure. (minutes) Prostaglandin is released when cells are mechanically deformed = primary response. (mediated by focal adhesion kinase mechanoreceptor in PDL cells) → PgE stimulates Osteoblasts & -clasts. 2. PDL cells under stress induce the formation of osteoclasts. Concentration of RANKL and OPG ↑. 3. Other chemical messengers particularly members of the cytokine family and nitric oxide (NO) and other cell regulators are involved. 4. Osteoclasts arrive in about 48 h and come in 2 waves: 1st from the local cell population. 2nd from distant areas via blood flow (more important). → Frontal resorption of the lamina dura at the pressure side. 5. Shortly later: Osteoblasts (recruited locally from progenitor cells in the PDL) form bone on the tension side & begin remodeling activity on the pressure side. - Tooth movement is more efficient and less painful than with heavy force. - Tooth movement in clinical practice usually proceeds in a stepwise fashion, because of the inevitable areas of undermining resorption even with light forces. → Attainment of a smooth progression of tooth movement is maybe unattainable with continuous forces. |
|---------------------|---|

| | |
|---------------------|--|
| Heavy force: | <ul style="list-style-type: none"> - Pain and necrosis of cellular element within the PDL. - Undermining resorption of alveolar bone near the affected tooth. <ol style="list-style-type: none"> 1. If the force is great enough to totally occlude blood vessels and cut off the blood supply, a sterile necrosis ensues within the compressed area. 2. Bone remodelling bordering the necrotic area of the PDL must be accomplished by cells derived from adjacent undamaged areas. → Cellular elements begin to invade the necrotic (hyalinized) area. 3. Undermining resorption: Osteoclasts appear within the adjacent bone marrow space and attack the underside of the bone immediately adjacent to the necrotic area. - Always some avascular = hyalinized areas in the PDL: (nomenclature: hyalinized because the tissue looks like hyalin cartilage in the histologic section) → Release pressure at intervals to maintain tissue vitality → Chew chewing gum the first 8h after orthodontic force is applied to reduce pain. - Delay in tooth movement occurs, if hyalinization and undermining resorption occur: <ul style="list-style-type: none"> o Delay in stimulation of cell differentiation within the marrow spaces. o A considerable thickness of bone must be removed from the underside before any tooth movement can take place. - Tooth movement with frontal resorption vs. undermining resorption. <p>With frontal resorption, a steady attack on the outer surface of the lamina dura results in smooth continuous tooth movement. With undermining resorption, there is a delay until the bone adjacent to the tooth can be removed. At that point, the tooth "jumps" to a new position, and if heavy force is maintained, there will again be a delay until a second round of undermining resorption can occur.</p> |
|---------------------|--|

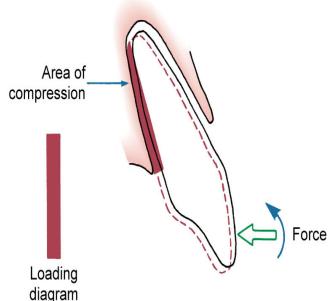

Effects of force distribution and types of tooth movement

- The biologic effect is determined by the amount of force delivered to a tooth and the area of PDL over which that force is distributed = **force or pressure per unit area**.

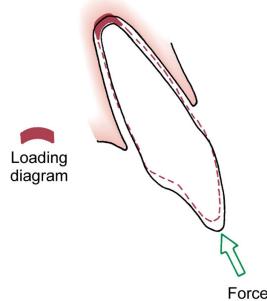

Tipping:

- Only $\frac{1}{2}$ of the PDL that could be loaded, actually is.
- Heavy pressure at the root apex and crest of the alveolar bone, nearly zero pressure at the center of resistance
- 50 g

Translation / bodily movement

Intrusion

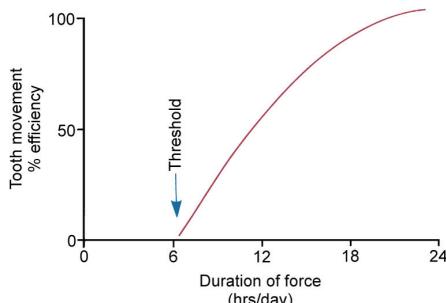

- Optimum forces for orthodontic tooth movement:

| Type of movement | Force (gm) |
|--------------------------------------|---------------|
| Tipping | 35-60 |
| Bodily movement (translation) | 70-120 |
| Root uprighting | 50-100 |
| Rotation | 35-60 |
| Extrusion | 35-60 |
| Intrusion | 10-20 |

- *Cave: Optimum forces have never been scientifically examined! Values are based only on experience and animal studies.*
- The values depend on the size of the tooth:
 - o Smaller values for incisors.
 - o Higher values for multirooted posterior teeth.
- The maximum force is often limited by an accompanying tipping movement to the basic movement: i.e. rotation along the long axis would have a greater value, but it is impossible to perform it without tipping.
- Teeth normally move continuous with an individual speed for each patient.
 - If movement interchanges with stops, there is something not correct: Notching of the wire, hyalinization...

Effects of force duration and force decay

- Continuous force 24 h/day produces the most efficient tooth movement.
- Threshold at about 6 hours to have an effect.

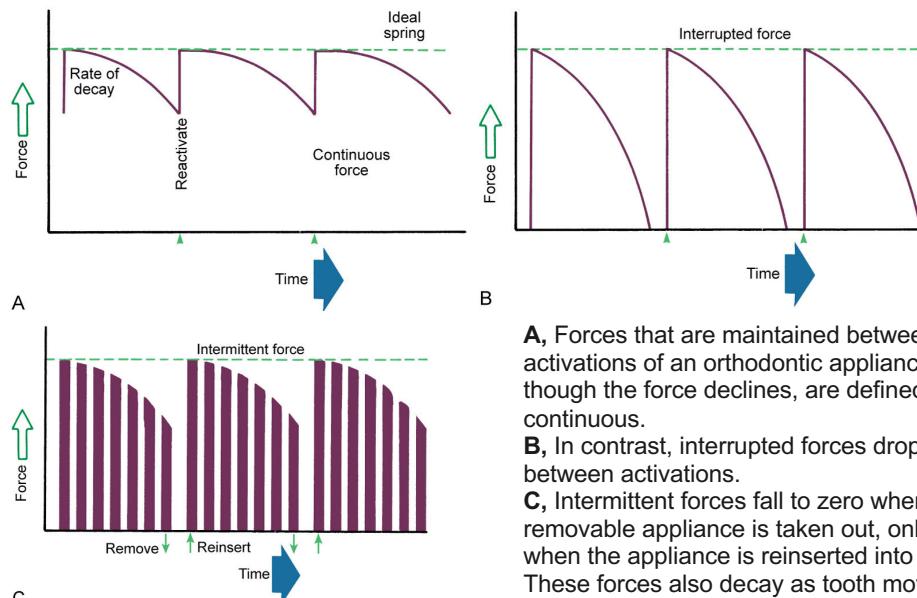

- Removable appliances:
 - o Minimum 4-6 h wear time to reach the threshold to initiate tooth movement:
= Time necessary until cyclic nucleotide levels (cAMP) in the PDL increase and second messengers are produced to stimulate cellular differentiation.
 - o Decreasing fractions of time → decreasing amount of tooth movement.
- Increasingly effective tooth movement is produced if force is maintained for longer durations.
- Sustained force:
Force must not be absolutely continuous, but be present for a considerable percentage of time.
- An ideal spring would maintain the same amount of force regardless of the distance a tooth has moved.
With real springs however, the force decays at least somewhat as tooth movement occurs.

$$F(x) = -kx. \quad k = \text{spring constant}, x = \text{activation}$$

- Classification of force by the rate of decay:

- o **Continuous:**
 - Force is maintained at some appreciable fraction of the original force from one visit to the next (forces are allowed to decline).
 - E.g. MBA, spring.
- o **Interrupted:**
 - Force levels decline to zero between activation.
 - E.g. MBA.
- o **Intermittent:**
 - Force levels decline abruptly to zero intermittently when an appliance is removed and then return to the original level (or less) some time later.
 - If tooth movement occurs, the force declines may up to zero.
→ Intermittent force can also be interrupted.
 - E.g. patient activated appliances: removable plates, HG...

- A**, Forces that are maintained between activations of an orthodontic appliance, even though the force declines, are defined as continuous.
B, In contrast, interrupted forces drop to zero between activations.
C, Intermittent forces fall to zero when a removable appliance is taken out, only to resume when the appliance is reinserted into the mouth. These forces also decay as tooth movement occurs.

- Heavy continuous forces should be avoided → damage to the teeth and the PDL.
(no time for PDL regeneration at the undermining resorption sites)
- Heavy intermittent forces are clinically acceptable though less efficient.
(hyalinization, undermining resorption, but some time for regeneration).
- Tooth movement is most efficient when light continuous forces are applied.
- Reactivation interval for orthodontic appliances:
 - o Not more frequent than at a **3-week interval**: Undermining resorptions require 7-14 days.
 - o Spring appliance with light continuous forces: **6-8 weeks**.
 - o Stiffer appliances creating undermining resorptions with force levels that drop to 0:
 - Tooth movement in the first 10 days.
 - + equal or longer period needed for PDL regeneration & repair.

Drug effects on the response to orthodontic force

- No drugs are available at the moment to speed up tooth movement.
Problem: Local application at the site where tooth movement is desired.
- Most studies examining drug effect on orthodontic tooth movement are animal studies:
 - o Species difference
 - o Age
 - o Relatively short intervention→ not reliable.
- Experimental **Prostaglandin** injection has shown some effect. Cave: Painful.
- Prostaglandin inhibitors:
 - **Phospholipids → (Phospholipase A2) Arachidonic acid → (Cyclooxygenase) Prostaglandin, Prostacyclins, Thromboxans**
 - **Phospholipids → (Phospholipase A2) Arachidonic acid → (Lipoxygenase) Leukotrienes**
 - **Eicosanoids** = Prostaglandines, Prostacyclins, Leukotriens and Thromboxans.
- Effect of Prostaglandine:
 - o Sensibilisation of nozireceptors
 - o Stimulation of inflammations
 - o Thermoregulation in the hypothalamus → fever
- **Corticosteroids:**
 - o Inhibit the formation of AA.
 - o Dose dependent effect, esp. for glucocorticoids. (Proffit says no effect)
- **NSAID:**
 - o Inhibit conversion of AA → Pg by inactivation of the cyclooxygenase (**Cox1 or Cox2**).
 - o Most analgesics (except acetaminophen (Tylenol), paracetamol).
 - o No interferences with tooth movement if used in low doses and short duration.
 - o Inhibition of tooth movement possible if applied in high doses over long time.
- **Relaxin:**
Effect is controversial: collagen synthesis ↓, collagen breakdown ↑.
- Drugs that increase brain levels of **acetylcholine** may accelerate tooth movement by affecting circulating hormone levels.
- **Tricyclic antidepressiva**
Anti-arrhythmic agents (e.g. Procain)
Anti-malarial drugs & Methylxanthines (to treat asthma) can affect Pg-synthesis and therefore tooth movement.
- **Phenytoin:**
 - o Anticonvulsant drug (bei Epilepsie & Herzrhythmusstörungen)
 - o Inhibits tooth movement in rats.
 - o Gingiva hyperplasia.
- **Tetracycline:**
 - o Inhibits osteoclast recruitment.
 - o **Doxycycline:** apical root resorptions ↓
Prescribed in case of dental trauma:
Children >8y (tooth crowns completed): **1st day: 100 mg, 2-10th day: 50 mg**
Adults: **1st day 200 mg, 2-10th day 100 mg.**
→ Always combine antibiotics with probiotics to reduce candida infections.
- **Estrogens:**
 - o Little or no effect on orthodontic tooth movement.
 - o Theory: Estrogens increases OPG release → potential inhibition of tooth movement.
- **Bisphosphonates:** inhibit tooth movement
 - = Synthetic analogues of **pyrophosphate** which bind to hydroxyapatite in bone.
 - Inhibit osteoclast mediated bone resorption by inactivating RANKL on osteoblast:
→ slower bone remodeling for tooth movement.
 - Incorporated in the bone for many years, but mostly at the surface in newly built bone.
Surface = faster elimination → orthodontic tx is possible after 3m without bisphosphonate therapy.
 - Risk for necrosis of the mandibular bone → avoid selective extractions.

Drugs with effect on apical root resorption:

- Thyroid hormone (Thyroxin) ↓
- Doxycycline ↓
- Nabumetadon ↓
- Bisphosphonates ↑ or ↓ (unclear, dose dependent)

Drugs inducing a gingiva hyperplasia:

- Phenytoin
- Ca channel blocker
- Ritalin
- Ciclosporin

Drugs inducing xerostomia:

- Antidepressiva
- Antiepileptics

Drugs changing the microbiota:

- Immunosuppressiva
- Inhaled steroids (asthma)

Inhibition of osteoclasts:

- Tetracyclines
- Bisphosphonates
- Calcitonin (acts directly on osteoclasts → activity ↓ / reduces the calcium blood level)
(Calcitonin, Vitamin D & PTH regulate together the blood level of calcium)
- OPG (Antagonist to RANKL)
- Denosumab (antibody that impedes the binding RANKL - RANK)
- Estrogens?

Activation of osteoclasts:

- RANKL
- Calcitriol (Vitamin D $1,25(OH)_2D_3$)
- PTH
- M-CSF
- Prostaglandin (dose depended)
- Leukotrienes

Effect of local injury: Corticotomy

- Idea: (*Frost, 1994*)
Bone remodeling is accelerated during wound healing via the **regional acceleratory phenomenon = RAP effect**.
- RAP effect (*Prof. Buschang*)
 - o Initiated by a pain stimulus
 - o Affects soft and hard tissue
 - o Vital healing process
 - o Can speed up tooth movement ↓
 - o Injury ↑ → tooth movement ↓
 - o Bone density ↓ → RAP ↑
- Time for bone healing depends on (*Prof. Buschang*)
 - o Extent of the injury
 - o Blood supply
 - o Stability of the segments
- **Corticotomy original concept:**
 1. Flap
 2. Vertical / facially / lingually cuts between and under the teeth that do not penetrate all the way through to the other side → = creating blocks of bone around a tooth for reposition.
 3. Apply force to create greenstick fractures of the bone.

Cave:

 - o Invasive
 - o Root apex does not move → teeth are tipped into position, not bodily moved.

Indication:

 - o Ankylosed teeth
 - o PFE teeth, if partial eruption took place
 - o Impacted canines
- **Corticotomy nowadays:**

Still a flap with fully exposed alveolar bone, but the recommended forces are lighter. Shift to AOO.
- **Accelerated osteogenic orthodontics AOO:**
 - o Areas of decortication are added over the facial surface of the alveolar bone which are covered with bone grafting material.
→ Try to generate new bone that allows facial directed movement of teeth without risk for gingival recessions (no data available to support this claim).

Cave:

 - o After a fracture, enough bone healing to allow release of fixation takes about 6 w, maturation of bone is largely completed in another 2 m.
→ Bone remodeling after corticotomy would be accelerated only for 2-4 m.
= Little time compared to the overall tx time.
→ Benefit is primarily in reduction of the time to align crowded teeth without extractions.
 - o Loss of alveolar bone height if no bone grafting is performed.
 - o Unsightly facial bruising.
 - o Whitening of the Gingiva.
 - o Unfavorable changes in the appearance of the gingiva after the extensive flaps.
 - o Possibility of gingival stripping.
 - o Not sufficient data for a good documentation that the procedure is safe.

→ No qualified tool for accelerated tooth movement.
- **PDL distraction:**
 1. Cuts are made in the wall of the socket of an extracted tooth.
 2. Neighbor teeth are moved into the place with a spring providing heavy force, so that the PDL is extremely stretched (nowadays light forces are preferred).
- **Modified corticotomy: Piezocision**
 1. Gingival incision between crowded incisors only on the facial side (no flap).
 2. Injury to the bone in that area is performed with a vibrating piezoelectric knife.
(penetration of the cortical bone and extend into the medullar bone)
 3. Tunneling the gingiva over the root allows to add a graft material if desired.

An isolated RCT (*Charavet, 2016*) shows a sign. shorter tx time, but the generalizability of the data is unclear.

Risk of root damage.

→ No qualified tool for accelerated tooth movement.

- **Microperforation:**

Screws are placed through the gingiva into interproximal alveolar bone and then removed:

→ try to create regional accelerated bone remodeling.

- No data published until now to document the effectiveness.
- Developed by a commercial company.
- If effective, the effect would rather be limited to a specific area rather than a whole arch.
(effort to drill that many holes)
- Effect limited to one week, because the insertion depth is very small.

- Space must be closed / “used” immediately after surgery! Otherwise surgery effects are lost.

- Simple tooth extraction: To prevent a round trip of the anterior teeth in premolar extraction cases, slice the tooth who is going to be extracted bevor extraction.

- **Fiberotomy:**

No influence on the speed of tooth movement.

- **Flap:** (*Prof. Buschang*)

30% faster tooth movement → proof that soft and hard tissues are important.

- Conclusions of the injury methods:

Cost-benefit ratio is only favorable for few patients + invasive tx approach & morbidity.

Other physical effects to accelerate tooth movement

- Vibration of the teeth:

- Should stimulate cell differentiation and maturation.
- **Accelodent:** 30 Hz high frequency vibration 20 min / day.
- **Propel device:** Higher frequency 5 min / day.

- Application of light to the alveolar process (phototherapy, Biolux):

- 800-850 nm wave length (about visible spectrum).
- 97% energy lost on the way to the alveolar bone.
- Energy should excite intracellular-enzymes and increase cellular activity in the PDL and bone:
→ Bone remodeling ↑ & tooth movement↑.

- Application of therapeutic ultrasound to the teeth and adjacent bone (Aevo device)

- Idea: Increase of the blood flow in treated areas → bone remodeling ↑ & tooth & root resorption ↓.
- Used in physical therapy to increase blood flow in muscles.

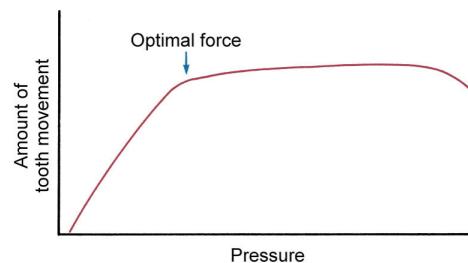

→ No evidence of effectiveness for all approaches at the moment

Anchorage and its control

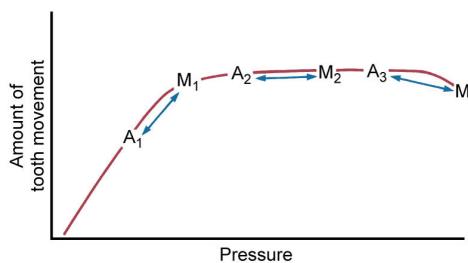

- Anchorage = resistance to unwanted tooth movement.

Relationship of tooth movement to force

- Reciprocal effects throughout the dental arches must be carefully analyzed, evaluated and controlled.
- Aim:
Concentrate the force needed for the tooth movement and dissipate the reaction force over as many other teeth as possible → keeping pressure in the PDL of anchor teeth low.
- The threshold for tooth movement is very small: $\geq 5-10 \text{ gm/mm}^2$.
- Tooth movement increases as pressure increases up to a point, remains at about the same level over a broad range and then may actually decline with extremely heavy pressure.
- Optimum force for orthodontic purposes is the lightest force that produces a maximum or near-maximum response. The ideal force magnitude depends on the way in which it is distributed to the PDL.

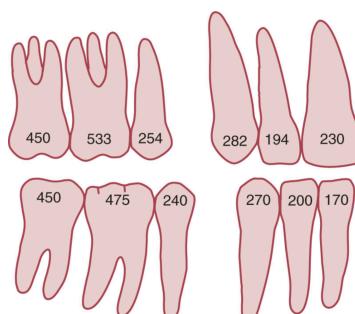

- Too much force destroys the effectiveness of reinforced anchorage by pulling the anchor teeth up on the flatter portion of the pressure response curve.
- Extreme force:
Anchor teeth might move more than the tooth which was desired to move.
(the smaller segment is placed beyond the greatest tooth movement range while the greater segment is still in it)
- Not clear, if a force maximum exists in reality.

Anchorage situations

- Root size↑ → area for force distribution ↑ = anchorage value ↑

The “anchorage value” of any tooth is roughly equivalent to its root surface area. As this diagram shows, the first molar and second premolar in each arch are approximately equal in surface area to the canine and two incisors.

| | |
|--|---|
| | <ul style="list-style-type: none"> - Reciprocal tooth movement: = Forces applied to the teeth and to the arch segments are equal and so is the force distribution in the PDL (must be the same PDL area). - Reinforced anchorage: = Adding more resistant units → the reaction force is distributed over a larger PDL area. - Stationary anchorage: Pitting bodily movement of one group of teeth against tipping of another. - Cortical anchorage: <ul style="list-style-type: none"> ○ Cortical bone = more resistant to resorption and remodeling. ○ Slowdown of tooth movement if a root contacts the cortical bone. (old extraction sides) ○ The facial and lingual cortical plate limits torque movements. ○ Cave: <ul style="list-style-type: none"> ▪ Tooth movement ↓. ▪ Penetration of the corticalis may occurs. ▪ Root resorptions are likely ○ Torquing molars to increase anchorage for cl.II elastics is no longer advisable. (risk of root resorptions ↑) - Skeletal anchorage: Implants (osseointegration is even not necessary), mini screws through the gingiva, bone anchors placed beneath the soft tissue → no movement. By using implants in the bone, it is possible to place force directly against the mx or mn and modify the growth. - Extraoral anchorage (HG): <ul style="list-style-type: none"> ○ 24 h wear is not possible. ○ Force against the teeth > optimal force. (heavy intermittent force against light continuous force of the MBA). - Intraoral anchorage: In theory additional anchorage can be obtained from the rugae area of the palate. However in fact, this is not very effective. - Muscular anchorage: <ul style="list-style-type: none"> ○ Lower lip ○ Periorale Weichteilmanschette - Two stage tx with tipping followed by uprighting can be used as a mean of controlling anchorage. |
|--|---|

| Deleterious effects of orthodontic force | |
|--|--|
| Tooth mobility | <ul style="list-style-type: none"> - PDL space is reorganized (detached from the bone & cementum and reattached later) → PDL space widens during orthodontic tx → tooth mobility ↑. - Some tooth mobility is normal. - Force ↑ = undermining resorption ↑ → mobility ↑. - A tooth with extreme mobility (if moved in a traumatic occlusion) during orthodontic tx should be taken out of the occlusion → corrects usually itself without any damage. |
| Pain | <ul style="list-style-type: none"> - Pain mechanism: <ul style="list-style-type: none"> 1. Tooth movement 2. Change of blood flow 3. Release of transmitters: Cytokines, substance P, Pg - Pain cascade: Stimulus → perception → pain assessment → pain reaction. - Pain origin: Sterile necrosis at the hyalinized areas of the PDL: → provokes inflammation at the apex + mild pulpititis. - Amount of force ↑ (= hyalinized areas ↑) → pain ↑. - If the force is appropriate, little or no immediate pain for the patient is felt at the activation of the appliance. - Several hours after reactivation, little pain is normal for 2-4 d. Teeth are sensitive to pressure. - Most severe pain = Pain from the initial activation. - <u>Influences on pain perception:</u> <ul style="list-style-type: none"> • Insufficient information before tx. • Adolescents > children & adults. adults > children. • Psychologic mood. • Cultural background. • Females > males. - <u>Pain management:</u> <ul style="list-style-type: none"> • Release pressure: Chew chewing gum the first 8 h after reactivation of the appliance: → Teeth are displaced to allow some blood flow through compressed areas. → No built-up of metabolic products stimulating pain receptors. • NSAID: Cave: Inhibits prostaglandin synthesis. • Acetaminophen (CH: paracetamol) <ul style="list-style-type: none"> ○ Acts centrally, no effect on the prostaglandin synthesis. ○ Does not reduce the inflammation at the apex: → less effective to control pain. ○ Prolonged use has potential to cause serious damage of renal function. • Placebo effect: Call patients at home the evening after they got the appliance. • Cognitive behavior therapy: Effective for patients who are willing to try. • Inform patients in advance about pain and how to handle it. • Low intensity laser: Effective, but application at home not feasible. • Transcutan nerve stimulation: Application difficult, no effect. - <u>Helps for patients with fear:</u> <ul style="list-style-type: none"> • Sweet stimulus (sugar or artificial) • Cold stimulus (napkin on the forehead) • Simple images (explain on an x-ray) • Sensitive treatment (tell - show - do) • Animate patients to speak • Make breaks |

| | |
|------------------|---|
| Allergies | <ul style="list-style-type: none"> - 4% of the children have an allergy → most of them grow them out. - Latex: <ul style="list-style-type: none"> • Can become life-threatening. • IgE mediated. - Chx: IgE mediated allergies possible. - Oral allergy syndrome: <ul style="list-style-type: none"> ○ Type 1 reaction. ○ Cross reaction for most cases: Patients are allergic to certain trees, which have similarities with food. - Nickel: Linsten & Kurol, 1997 <ul style="list-style-type: none"> • 20-40 µ gm/d nickel is released from an orthodontic appliance versus daily nickel intake of 300-500 µ gm/d by the nutrition (cacao beans, nuts, apple seeds). • The mucosa reacts different to nickel exposure than the skin: <ul style="list-style-type: none"> ▪ The skin is more acid than the mucosa → more formation of potential allergenic nickel sulfate. ▪ Cave patch test: Toxicology, dilution of some substances is difficult. ▪ → 20% US-population show skin reaction, but mostly no mucosa reaction. • Nickel test from the saliva are not reliable: dilution, regional differences. • Nickel in orthodontic appliances is more inert than in jewelry. • No difference in nickel release of ss or niti wires. • Nickel release from an orthodontic appliance does not increase the concentration of nickel in the blood. • Exposure of nickel by an orthodontic appliance: <ul style="list-style-type: none"> ▪ Can introduce a tolerance to later nickel exposure. ▪ Can stimulate a severe nickel sensitivity overreaction. • Piercings can increase the sensibility to nickel. • Incidence of nickel allergy: <ul style="list-style-type: none"> ▪ Girls: up to 30% (correlation with ear piercing) ▪ Boys: up to 4-19% • Symptoms of nickel allergy: Widespread erythema and swelling of oral tissues 1-2 days after an appliance is placed. • Clinical handling of nickel allergies: <ul style="list-style-type: none"> ▪ Bond 2 brackets for testing. ▪ Replace NiTi and SS material with titanium brackets and TMA wires. - Allergy types: <ul style="list-style-type: none"> • Type 1: <ul style="list-style-type: none"> • IgE mediated: IgE binds at the surface of mast cells → release of inflammation mediators. • Acute. • Skin test, IgE serum test. • Symptoms: Urticaria, angioedema, respiration problems. • Examples: Food allergy, bee allergy, latex. • Type 2: <ul style="list-style-type: none"> • Antibody mediated. • Semi-retarded. • Type 3: <ul style="list-style-type: none"> • Antibody mediated via the serum. • Type 4: <ul style="list-style-type: none"> • Cell mediated: <ol style="list-style-type: none"> 1. Haptene (part of the antigen) bind to dendritic cells. 2. Cells migrate into the lymph nodes and activate T-cells. 3. Reaction if the antigen binds again. |
|------------------|---|

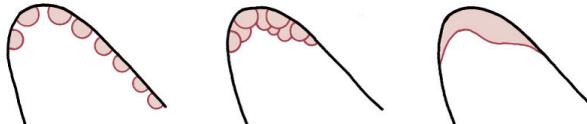

| | |
|----------------------------------|--|
| | <ul style="list-style-type: none"> • Retarded. • Patch test. • Symptoms: Exanthema, bullous reactions, hemolysis, cytopenia. • Examples: Drug reactions. <p>- <u>Anaphylaxis therapy:</u> Adrenalin injection: Effect > 1 min. <ul style="list-style-type: none"> ○ <25 kg: 0.15 mg ○ >25 kg: 30 mg Antihistaminika: Effect > 30 min. <ul style="list-style-type: none"> ○ ≤6 y: 5 mg Xyzal ○ ≥6 y: 10 mg Xyzal Cortison: Effect > 60 min. <ul style="list-style-type: none"> ○ Prendison 2mg / kg body weight </p> |
| Effects on the pulp | <ul style="list-style-type: none"> - Mild pulpitis as a modest and transient inflammatory response: → No long-term significance. - Loss of vitality is mostly related to a prior history of trauma, worsened by too heavy force application: Large abrupt apex movements can strangle blood vessels as they enter the root. - Excessive tipping / torquing of incisors can move the apex out of the bone and harm tooth vitality. - Endodontic treated teeth can be moved normally. (PDL is the key factor to movement and not the pulp). - Severe root resorptions of root treated teeth should not be expected. Exception: Teeth with a severe intrusion trauma and root tx. (less resorption if CaOH₂ filling is maintained during orthodontic tx). - Trauma teeth with root filling: More prone for "natural" RR without orthodontic force application, but not more prone for RR due to orthodontic force. |
| Effects on root structure | <ul style="list-style-type: none"> - Some remodeling of the cementum and the adjacent bone is usual: → The cementum is marked when it touches a hyalinized area → resorption → reparation. - Shortening of the root occurs when cavities coalesce at the apex so that peninsulas of root structure are cut off as an island → the islands resorb → net loss of root length although the repair process places new cementum over the residual root surface → roots become shorter, but not thinner although both the sides and the apex experience root resorptions.  <ul style="list-style-type: none"> - Categories of root resorption: (Kaley, 1991) <ol style="list-style-type: none"> 1. Slight blunting of the apex. 2. Moderate resorptions, ≤ 1/4 of root length. 3. Severe resorptions, ≥ 1/4 root length. - <u>Moderate generalized resorptions:</u> <ul style="list-style-type: none"> • Experienced by most of the patients, but in most cases almost imperceptible and clinically insignificant. • Tx duration ↑ → Resorptions ↑. • Maxillary incisors > other teeth. |

TABLE 8.4 Average Root Length Change

Data from Kennedy DB, Joondeph DR, Osterburg SK, et al. Am J Orthod. 1983;84:183.

| | MAXILLARY | | MANDIBULAR | |
|----------------------|-----------------|----------|-----------------|----------|
| | Serial Ext Plus | Late Ext | Serial Ext Plus | Late Ext |
| Central incisor | -1.5 | -2.0 | -1.0 | -1.5 |
| Lateral incisor | -2.0 | -2.5 | -1.0 | -1.0 |
| Canine | -1.0 | -1.5 | -0.5 | -1.0 |
| Second premolar | -0.5 | -1.5 | -0.5 | -1.5 |
| First molar (mesial) | -0.5 | -1.0 | -0.5 | -1.5 |
| ext, Extraction. | | | | |

- Severe generalized resorptions:
 - Rare, etiology unknown.
 - Some patients are prone to root resorptions even without orthodontic tx, probably due to genetics.
 - Risk ↑ if evidence of root resorption exists already before tx.
 - Risk factors: :
 - Conical roots
 - Pointed apices
 - Distorted teeth form (dilacerations)
 - History of trauma with or without root filling
- Severe localized resorption:
 - Caused by orthodontic tx: Excessive force, prolonged duration.
 - Maxillary incisors 3% affected, vs. <1% for all other teeth.
 - Make an OPT 6-9 m into tx to evaluate the resorption at that time.
→ Good predictor for the amount of future root resorptions.
Good prediction if: (*Artun, 2009*)
 - 6 m, no incisor > 1 mm apical root resorption
 - 12m, no incisor > 2 mm apical root resorption

TABLE 8.6 Risk Factors for Severe Root Resorption, Maxillary Incisors
Data from Kaley JD, Phillips C. *Angle Orthod.* 1991;61:125–131.

| Factor | Probability | Odds Ratio |
|-----------------------------|-------------|------------|
| Lingual plate approximation | .001 | 20 |
| Maxillary surgery | .002 | 8 |
| Torque | .01 | 4.5 |
| Extraction | .01 | .5 |
| Mandibular surgery | .05 | 3.6 |

Lingual plate approximation largely explains the other risk factors.

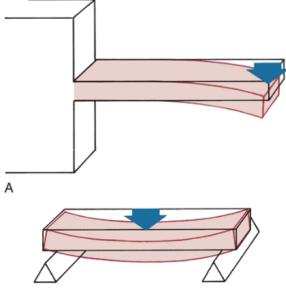

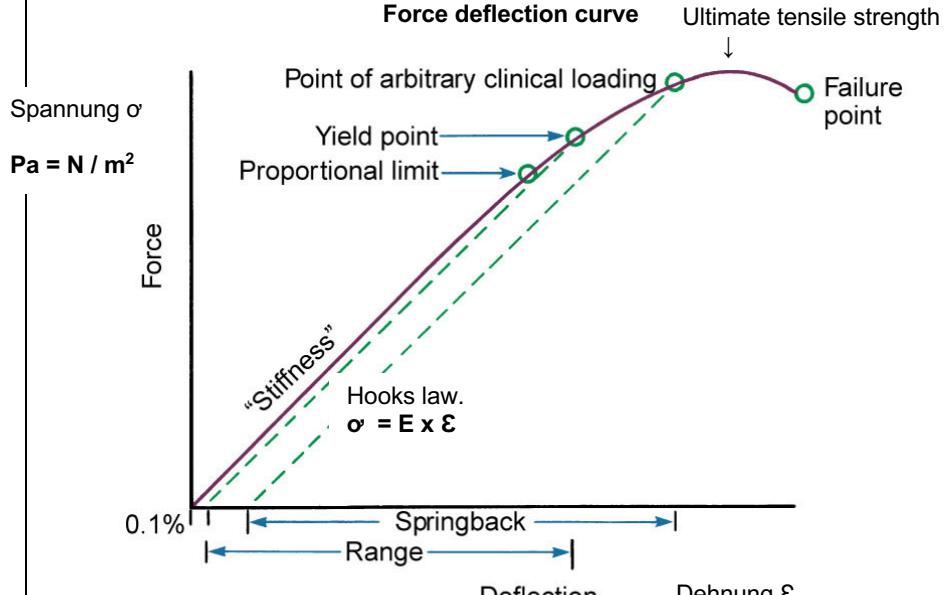

- Patient related risk factors:
 - Genetic (IL-1 polymorphisms)
 - Personal disposition (makes up to $\frac{1}{2}$ to $\frac{2}{3}$)
 - Prior apical root resorptions
 - Trauma
(more root resorptions in general, but not more apical root resorptions)
 - Systemic factors:
 - Drugs:
Nabumetone ↓, Doxycycline ↓, Bisphosphonates ↑ / ↓, Thyroxin ↓
 - Hormone deficit
 - Hypothyroidism (thyroxin deficit)
 - Hypopituitarism
 - Asthma
- Treatment related risk factors:
 - Length of the tx
 - Force magnitude
 - Force direction (intrusion, torque)
 - Force application protocol (continuous, intermittent...)
 - Amount of apex movement
 - Root morphology
 - Proximity to the compacta
- Effect of root resorptions on attachment loss. (*Kalkwarf, 1986*):
 - **4 mm apical root resorption = 20% attachment loss.**
 - **3 mm apical root resorption = 1 mm crestal bone loss.**
 - **After 2 mm, every additional 2 mm = 1 mm crestal bone loss.**
- Retention:
 - Root length <10 mm post-orthodontics:
→ increased mobility possible → splinting is indicated.
 - Root length ≥10 mm post-orthodontics:
→ Teeth remain stable if the periodontium is healthy.

| | |
|---|---|
| Effects of tx on the height of alveolar bone | <ul style="list-style-type: none"> - Almost never excessive loss of crestal bone height: <ul style="list-style-type: none"> o Average < 0.5 mm o Never > 1 mm o Greatest changes at extraction sites. o Exception: Tooth movement in the presence of active periodontal disease. - Position of the teeth determine the position of the alveolar bone. - Tooth movement can be used to create the alveolar bone needed for an implant or treat intraosseous pocket. E.g.: extrusion of a hopeless teeth to create bone formation. → Gingival border moves with the tooth but the mucogingival border not always → width of keratinized tissue ↑. - Early extraction of teeth or congenitally missing teeth = risk for alveolar bone defects which cannot become overcome by later orthodontic tx, if another tooth is not quickly moved into the site.5 - Bone height tends to be lost if a tooth is intruded. - Intrusion of periodontally involved teeth: <ul style="list-style-type: none"> o Pocket depth could be reduced only if teeth could be intruded without compensatory changes (difficult). o Reattachment of the PDL or more extensive bony support does not occur. Only a long junctional epithelium is created. |
| Effects of tx on the Parodont | <ul style="list-style-type: none"> - Recessions ↑: $\Delta + 0.03$ mm (clin. not sign.) - Alveolar bone dehiscence: $\Delta - 0.13$ mm (clin. not sign.) - Probing depth ↑: $\Delta + 0.23$ mm (clin. not sign.) - Plaque control ↑ - Gingivitis ↓ - Tooth with bands never recover to their pre-tx periodontal indices + shift of the microflora towards an anerobe spectrum. → Orthodontics can lead to a slight loss of attachment, but improve the oral hygiene. - <i>Ghijssels 2014:</i> Not all periodontal parameter return to pre-tx level. |
| Enamel demineralization | <ul style="list-style-type: none"> - Incidence white spot lesions: 50-70% <ul style="list-style-type: none"> o After orthodontics: ≥72% → 2.3% cavities 4.2 lesions per patient o Without orthodontics: 63% - Some demineralizations are found nearly in every orthodontic patient. - Check with light-induced fluorescence for a more accurate diagnosis. - After debonding some natural remineralization occurs, but the lesions usually don't regenerate completely. - Regeneration of the demineralization is possible in the first year and in the 1st to 2nd year, but afterwards there is normally no further improvement. - Risk factors: Multifactorial <ul style="list-style-type: none"> o Young age at the start of tx o Poor oral hygiene at the start of tx o Citations for poor hygiene during tx o Nutrition o Drugs → xerostomia (antiepileptics, antidepressants) o Long treatment o Bond / cement failure around brackets / bands o Extensive etching o Fixed buccal appliance (compared to a lingual appliance) - Prevention: <ul style="list-style-type: none"> o F- containing tooth paste. o Fluoridated water. o 0.05% sodium fluoride rinse. o F- varnish every 6 m (or more with high risk patients). o Short term daily chx rinse program (14 days). Cave: staining. o CPP-ACP: Casein phosphopeptide amorphous calcium phosphate. → Has the potential for remineralization. o Maintenance of a good oral hygiene at least 3 m before the start of orthodontic tx. o Oral hygiene on a high level for min. 3 months before orthodontic tx. |

- F- releasing bonding material:
No good evidence that they are effective against white spot formation around brackets.
- Glass-ionomer cement:
Absorbs F- when it is provided and then gradually discharges it.
- Glattflächenversiegler:
Controversial discussed.
- Therapy:
 - o Wait 2 months after appliance removal for remineralization with normal oral hygiene.
 - o Duraphat tooth paste 5000 ppm/F-
 - o Infiltration: Icon®
 - o Acid abrasion
 - o Bleaching
 - o Restorative tx: Fillings, veneers, crowns.
- Caries index
 0. ø caries
 1. Caries pm/molars occlusal
 2. Caries pm/molars approximal
 3. Caries anterior teeth
 4. Caries on buccal surfaces
 5. Completely destroyed carious teeth

Proffit Chapter 9:

Mechanical Principles in Orthodontic Force Control

| Basic properties of elastic materials | |
|---|--|
| Stress | = Internal distribution of the load, defined as force per unit of an area. $N/m^2 = Pa$ (Pascal) |
| Strain (load directed along the long axis) | = Internal distortion produced by the load, defined as deflection per unit length = $\Delta L/L$. - Stress-Strain response to an external load defines the elastic behavior. - External force and deflection are measured with a beam. → Internal stress and strain can be calculated from these values considering the length & the cross-sectional area of the beam. - General shapes of force-deflection (Belastung rechtwinklig zur Längsachse) and stress-strain (Belastung in Längsachse) |
| Force deflection curve (load directed perpendicular to the long axis) | <ul style="list-style-type: none"> - Differentiate: cantilever vs. supported beam.  <ul style="list-style-type: none"> - Important properties of a beam material for orthodontics: <ul style="list-style-type: none"> • Strength Strength = Stiffness x Range • Stiffness • Range - The properties can be represented by a stress-strain or force-deflection diagram. (general shape of the curve is similar) <p style="text-align: center;">Force deflection curve</p>  <p>The graph illustrates the mechanical behavior of a beam under load. The vertical axis is labeled "Spannung σ" and "Pa = N / m²". The horizontal axis is labeled "Deflection" and "$\Delta L / L$ in %". The curve shows the relationship between force and deflection, with key points marked: "Point of arbitrary clinical loading", "Yield point", "Proportional limit", "Ultimate tensile strength" (indicated by a downward arrow), and "Failure point". A dashed green line represents the linear relationship according to Hooke's law: $\sigma = E \times \epsilon$. Other labels include "Springback" and "Range" on the deflection axis, and "0.1%" on the force axis.</p> <ul style="list-style-type: none"> - Strength: <ul style="list-style-type: none"> • Strength = Stiffness x Range • Measured in units of stress: SI unit = Pascal (Pa) → 1 Pa = 1 N/m² • English unit = gm/cm² → 100 gm/cm² = 1 N/cm² = 10.197 Mpa = 145 psi |

| | |
|----------------------------|--|
| | <ul style="list-style-type: none"> - Proportional limit: <ul style="list-style-type: none"> • Highest point where stress and strain still have a linear relationship known as Hooke's law: $\sigma = E \times \epsilon$ • Determination of the point is difficult. - Elastic limit: Unit N/mm² or % <ul style="list-style-type: none"> • Lies between the proportional limit and the yield point. • The deformation is fully reversible, but the force/deflection ratio no longer proportional. - Yield strength: <ul style="list-style-type: none"> • Intersection of the stress-strain curve with a parallel line offset at 0.1% strain. • Strain were 0.1% plastic deformation occurs. (defined, because precise definition of the proportional limit is difficult) • If a wire is deflected after the yield point (here point of arbitrary clinical loading) springback occurs, but the wire no longer returns to its original shape. - Range (mm): (dt. Arbeitsbereich) <ul style="list-style-type: none"> • Distance along the X-axis to the point at which permanent deformation occurs (usually taken at the yield point). - Failure Point: Wire breaks. - Ultimate tensile strength: <ul style="list-style-type: none"> • Maximum load which the wire can sustain: → An increase of the strain does not increase the stress. • Reached after some permanent deformation. (greater than the yield strength) • Maximum force the wire can deliver if used as a spring. - Springback: <ul style="list-style-type: none"> • Measured along the x-axis: = Extent to which a wire goes back to its original force after deflection • Useful springback occurs, if the wire no longer returns to its original shape when it is deflected beyond the yield point. |
| Stress-strain curve | <p>Stress</p> <p>Strain</p> <p>Ultimate tensile strength</p> <p>Yield strength</p> <p>Proportional limit</p> <p>Range</p> <p>E</p> <p>Stiffness $\propto E$</p> <p>Springiness $\propto 1/E$</p> <p>$E = \Delta \text{ stress} / \Delta \text{ strain}$</p> <p>0.1%</p> <p>Failure point</p> <p>Yield point</p> <p>Ultimate tensile strength</p> <p>Yield strength</p> <p>Proportional limit</p> <p>Range</p> <p>E</p> <p>Stiffness $\propto E$</p> <p>Springiness $\propto 1/E$</p> <p>$E = \Delta \text{ stress} / \Delta \text{ strain}$</p> <p>0.1%</p> <p>Failure point</p> <p>Yield point</p> |

^cApparent modulus, calculated.
A-NiTi, Austenitic nickel–titanium; M-NiTi, martensitic nickel–titanium.

| | |
|------------------------|--|
| Stainless steel | <ul style="list-style-type: none"> - Typical composition of stainless steel: (18/8 ss) <ul style="list-style-type: none"> ○ 74% SS ○ 18% Chromium (Korrosionsschutz) ○ 8% Nickel (verbessert Verarbeitung) ○ < 0.2% C Kohlenstoff (verbessert Kaltverformungs-Eigenschaften) - Better strength and springiness with equivalent corrosion resistance compared to gold. - Properties can be controlled over a wide range: <ul style="list-style-type: none"> • Annealing (glühen) → Steel is softened. • Yield strength can be enhanced at the cost of formability. • Wärmbehandlung: <ul style="list-style-type: none"> ○ Spannungsarmglühen: <ul style="list-style-type: none"> ▪ Reduktion der inneren Spannungen, keine Bildung eines neuen Gefüges. ▪ Federrate und E-Modul konstant. ▪ Proportionalitätsgrenze ↑ ○ Rekristallisationsglühen (Weichglühen): <ul style="list-style-type: none"> ▪ Härte ↓ / Federrate ↓ / E-Modul ↓ |
|------------------------|--|

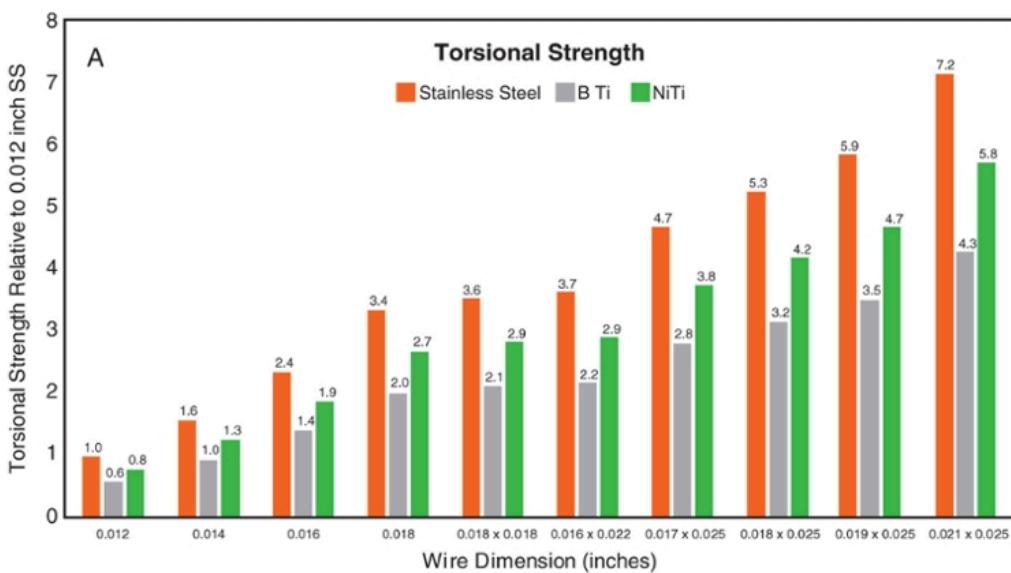

| | |
|---|--|
| | <ul style="list-style-type: none"> ▪ Treibende Kraft: Spannung an den Korngrenzen / Bildung eines neuen Gefüges ○ Ausscheidungshärtung: <ul style="list-style-type: none"> ▪ Funktioniert nur für Legierungen, die im Zustandsdiagramm eine Mischungslücke aufweisen, z.B. Elgiloy. ▪ Durch bestimme Wärmezufuhr erhöht man die Härte = E ↑. ▪ Homogener Mischkristall → Entmischungszone (Gitterverspannungen) → intrakristalline Ausscheidung. ● Cold working → Steel is hardened. <ul style="list-style-type: none"> ○ Wire strained beyond the elastic limit → plastic deformation. If the strain is removed, the stress returns to 0, but plastic deformation is set into the wire. ○ At subsequent reloading: E-Modul ↑ Elastic limit ↑, Ultimate tensile strength ↑ BUT the distance between those points ↓ = Ductility ↓ |
| Cobalt-chromium alloys (Elgiloy) | <ul style="list-style-type: none"> - Composition: <ul style="list-style-type: none"> ○ 40% Copper ○ 20% Chrome ○ 15% Steel ○ 15% Nickel ○ 7% Molybdenum ○ 2% Mangan - Softer and therefore more formable than SS. - Wire can be hardened to the level of stainless steel by heat tx after being shaped. - Disappeared: More expensive than steel, extra step of heat tx required. |
| | |

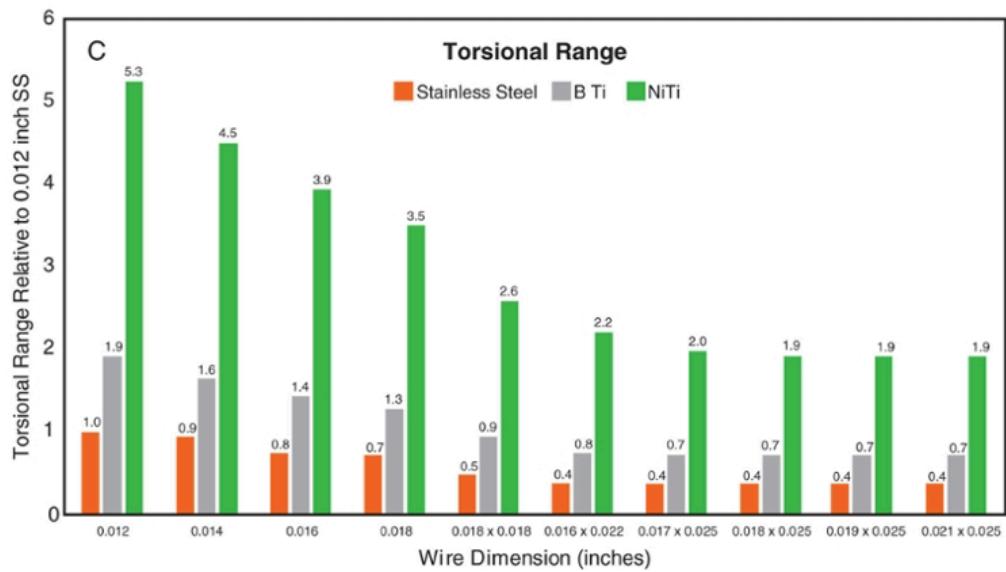

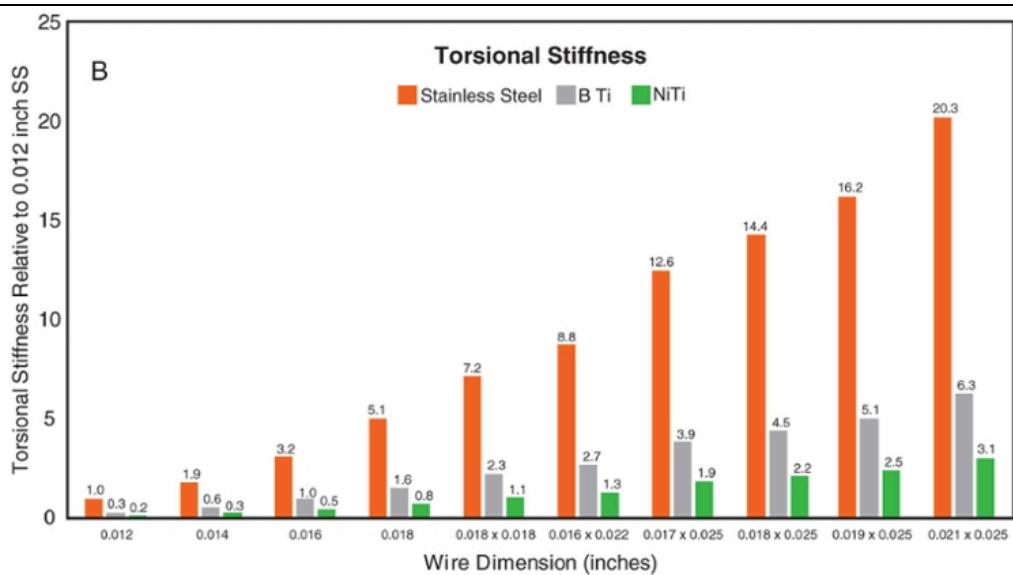

d

| | |
|---|--|
| Nickel-titanium alloys 55% Ni 45% Ti | <ul style="list-style-type: none"> - Apply light force over a large range of activation. - Exist in 2 crystal structures: <ul style="list-style-type: none"> • At lower temperature, higher stress: Martensit form more stable. • Higher temperature, lower stress: Austenitic form more stable. • Transition between the two structures is fully reversible and occurs at low temperature (room temperature). <ul style="list-style-type: none"> Note: Temperature can be modified $\pm 100^{\circ}\text{C}$ by slight changes of the alloy composition. → Heating Niti wires with a lighter, allows to bend circles. • Thermoelasticity = Temperature-induced change in th crystal structure. Difficult to exploit in orthodontics. (temperature cannot be controlled during alignment). - Shape memory: <ul style="list-style-type: none"> • <i>Thermal</i> reaction. • A shape is given to the material at a temperature above the m-a transition. When the material is cooled down it can be plastically deformed in the martensitic state. The original form is however restored, when the material is heated to regain an austenitic structure. - Superelasticity (=Pseudoelasticity): <ul style="list-style-type: none"> • <i>Mechanical</i> reaction. • NiTi wires withstand very large reversible strain due to the m-a-transformation → nonlinear stress-strain curve due to a reversible change in the internal structure after a certain amount of deformation. • “Normal” materials can be reversibly deformed only by stretching interatomic bonds. • Materials displaying superelasticity are austenitic alloys that undergo a transition to martensite in response to stress. (the transition temperature must be lower than room temperature for the austenite phase to exist clinically) • The archwires exert about the same force whether they are deflected a relatively small or large distance → ideal for leveling. |
| | <p>Bending moment versus deflection plotted for 16-mil orthodontic wires (solid red, stainless steel; dashed red, stabilized martensitic nickel-titanium [M-NiTi]; green, austenitic NiTi [A-NiTi]). Note that after an initial force level is reached, A-NiTi has a considerably flatter load-deflection curve and greater springback than M-NiTi, which in turn has much more springback than steel.</p> <ul style="list-style-type: none"> - Bending of NiTi wires is not possible because they do not undergo plastic deformation until they are remarkably deformed. NiTi wires can be shaped and their properties altered with heat tx (memorymarker pliers) → performed for lingual orthodontics. <p>Stress strain curve illustrating superelasticity due to the a-m transition for a A-NiTi wire</p> <ul style="list-style-type: none"> - A-B: Purely elastic deformation of the austenitic phase (in this phase A-NiTi is stiffer than M-NiTi). - B: Minimum stress at which transformation to the martensitic phase starts to occur. - C: The transformation is completed. |

| | |
|---------------------|---|
| | <ul style="list-style-type: none"> - C-D: Martensitic structure deforms elastically. - D: Yield stress of the martensitic phase is reached, and the material deforms plastically. - E: Failure occurs. - C'-F: Elastic unloading of the martensitic structure occurs if the stress is released before reaching point D. - F: Minimum stress on which the stress-induced martensitic structure on unloading can exist, and at that point the reverse transformation to austenite begins, - G: Austenitic structure is completely restored. - G-H: Elastic unloading of the austenite phase. A small portion of the total strain may not be recovered because of irreversible changes during loading or unloading. <p>- M-NiTi:</p> <ul style="list-style-type: none"> • = Original NiTi wires. • E = 28-41 MPa • Stabilized in the m-form. (ϕ phase transition effect) • Indicated for later stages of tx, when flexible but larger and stiffer wires are needed. <p>- A-NiTi:</p> <ul style="list-style-type: none"> • E = 80 MPa (\rightarrow stiffer than M-NiTi if purely elastic deformed) • Superelasticity and/or memory effect due to m-a-transition. • Wire bending is not possible / only with memory making pliers (Sander, 1996). (shape and properties can be changed by heat tx) • Ideal for orthodontics: Long range of activation with relative constant force. • Rectangular A-NiTi does not have enough stiffness for torque movements. • Examples: Sentinel, Copper NiTi <p>• Unloading curve changes at different activations, i.e. the unloading stiffness is affected by the degree of activation. (not the case for M-NiTi, Beta-Titanium or ss)</p> |
| Beta-titanium (TMA) | <ul style="list-style-type: none"> - Composition: <ul style="list-style-type: none"> ○ 79% Titan ○ 11% Molybdenum ○ 6% Zirconium ○ 4% Zinn - Titanium exist in 2 forms: <ul style="list-style-type: none"> • Alpha-titanium: Hexagonal. • Beta-titanium: Cubic, 17% more volume. • Transformation temperature is normally at 882°C. Modification / stabilization possible by adding certain elements (e.g. Molybdenum). |

| | <ul style="list-style-type: none"> - Properties: <ul style="list-style-type: none"> • Intermediate between stainless steel and M-NiTi. • Combination of strength and springiness. • Good formability. → Excellent for auxiliary springs, intermediate and finishing archwires. | | | | | | | | | | | | | | | | |
|--------------------------------------|---|----------|--------|------|--------|----------|-----|-----|-----|-----------|-----|-----|-----|-------|-----|-----|-----|
| Composite plastics | <ul style="list-style-type: none"> - Desirable properties in laboratory. - Problems with stability and performance under intraoral conditions. | | | | | | | | | | | | | | | | |
| Comparison of contemporary archwires | <ul style="list-style-type: none"> - Hooke's law: $\sigma = E \times \epsilon$ (stress is proportional to strain up to the elastics limit) Applies to all orthodontic wires except A-NiTi (non-linear response). - Strength ratio = strength A / strength B - Stiffness ratio = Stiffness A / Stiffness B - Range ratio = Range A / Range B - Cave: <ul style="list-style-type: none"> • Bending describes round wires in orthodontic application, but bending and torsional stress exists when a rectangular wire is placed into a rectangular attachment on teeth. • Ratios apply to the linear portion of the load-deflections curve. They do not describe the behavior of wires which are stressed beyond the elastic limit but have a useful springback characteristic. | | | | | | | | | | | | | | | | |

| | <ul style="list-style-type: none"> - Hebelarm: <ul style="list-style-type: none"> • Kraft nimmt in der 3. Potenz ab bei einer Längenänderung. • Das Moment nimmt proportional ab zur Längenänderung. |
| Control orthodontic force by varying materials and size / shape of archwires | <ul style="list-style-type: none"> - Change the length (springiness ↑↑, strength ↓). - Combine 2 or more strands of a small and therefore springy wire: <ul style="list-style-type: none"> • Strength ↑, springiness ↓ • Properties depend on the characteristics of the individual wire strands and how tightly they are woven together. • → Genesis of the “twin wire” appliance. • Multistrain wires are widely displaced for most applications by NiTi wires. - Use a sequence of wires with about the same size from different materials. - Spring design: <ul style="list-style-type: none"> • Adequate strength → use steel wire. (TMA ~= ½ force of ss) • Increase the length to obtain more desirable mechanical properties. |

| Other sources of elastic force | |
|--------------------------------|---|
| Clear aligners | <ul style="list-style-type: none"> - Material can store enough energy to create tooth movement. - The thermostretching process of the material during fabrication can influence the aligners thickness and therefore maybe their force delivery characteristics. - Elastic range limited to ~ 0.2 mm. - Subject to stress relaxation and water absorption. - Invisalign smart track material: Relative constant force delivery over 14 days.  |
| Rubber | <ul style="list-style-type: none"> - Great elastic range. - Water absorption. - Disintegration intraoral: Gum rubber deteriorates in the mouth within a couple of hours. - Elasticity is lost after 12-24 h. - No longer used. <p>- Superseded rubber by latex:</p> <ul style="list-style-type: none"> • → Performance life 4-6x longer compared to rubber only. • Standard nowadays instead of rubber. Exception: latex allergy. |
| Plastic material | <ul style="list-style-type: none"> - Elastomers deteriorate in elastic performance, but perform quite well for: <ul style="list-style-type: none"> • Holding archwires in place. • Closure of small spaces. - Forces decay rapidly → interrupted force. |
| Magnets | <ul style="list-style-type: none"> - Produced from rare earth materials which are potentially toxic. - No cytotoxic effect is observed, if magnets in sealed cases are placed intraoral. - Little if any biologic effect from small magnets to generate orthodontic force. - Force between a pair of magnets follows the inverse square law: → Force levels are quickly too small / large as soon as teeth move. |

| Design factors in orthodontic appliances | |
|--|--|
| Force | <ul style="list-style-type: none"> - = Load applied to an object. - Unit = Newton (mass x acceleration of gravity. $1\text{ N} = 1\text{kg} \times 1\text{m/s}^2$). - Force of gravity = 9.81 m/s^2 - Clinically measured in weight units. $1\text{N} = 100\text{ gm}$. → Cave: Force ≠ mass. - Forces in orthodontics consist of a: <ul style="list-style-type: none"> • Magnitude N / grams in orthodontics • Direction • Point of force application |
| Newton Laws | <ol style="list-style-type: none"> Trägheitsprinzip: Ohne Krafteinwirkung verbleibt ein Körper im gleichbleibenden Zustand. Aktionsprinzip: Die Beschleunigung eines Körpers ist proportional zur einwirkenden Kraft. Actio - Reactio = Gesetz der Mechanik. $\sum \text{Momente} = 0 \mid \sum \text{Kräfte} = 0$. (Die Summe aller Kräfte & Drehmomente in einem geschlossenen System ist = 0.) |
| Center of resistance | <ul style="list-style-type: none"> - = Point at which the resistance to movement can be concentrated for mathematical analysis. - Determined by the nature of the external constraints. → The surface geometry is more important than the distribution of the density. - For an object in the free space, center of resistance = center of mass. - For a tooth, Cres = approx. midpoint of the embedded portion of the root. (Note: Single rooted teeth: borderline between the cervical & middle root third, 4/10) - Force through the Cres creates pure bodily movement (=translation) without any rotation.  |
| Moment | <ul style="list-style-type: none"> - Moment = force x moment arm Unit: gram millimeter. - Moment arm = perpendicular distance from the point of force application to the center of resistance. - Moment: <ul style="list-style-type: none"> • = A measure for the tendency to rotate an object around a point. • Generated by forces acting distant (not trough) the center of resistance. • Always created if the line of action of an applied force does not pass through the center of resistance. - Force application closer to the Cres = moment arm ↓ → moment ↓. |
| Couple | <ul style="list-style-type: none"> - = Two forces equal in magnitude and opposite in direction, but not on the same line. → Pure moment (the translational effects of the forces are canceled). - The combination of a force + a couple can change the way an object rotates while it is being moved. |
| Center of rotation | <ul style="list-style-type: none"> - = Point around which rotation occurs when an object is being moved. - Can be controlled and located by application of two forces simultaneously. - Eccentricity of the force ↑ = Distance between Crot & Cres ↓   <p>- Definition of the Crot: 1. Contact 2x2 moving points and draw the perpendiculars in the middle 2. Cross-section of the two perpendiculars = Crot.</p> |

Mc/Mf ratios and control of root position

- Control of root position during tooth movement needs a force to move the tooth (Mf) and a couple to produce the counterbalancing moment for the control of the root position (Mc).
 - A two-point contact is necessary for control of the root's position.
- Rectangular archwires in a rectangular bracket slot :
 - The entire force system can be produced with a single wire.
 - Addition of torque can increase the counterbalancing movement.
- Round wires in bracket slots:
 - An auxiliary spring is needed to produce a torqueing couple.

| | |
|-------------------|---|
| $M_C/M_F = 0$ | Pure tipping (tooth rotates around center of resistance) |
| $0 < M_C/M_F < 1$ | Controlled tipping (inclination of tooth changes but the center of rotation is displaced away from the center of resistance, and the root and crown move in the same direction) |
| $M_C/M_F = 1$ | Bodily movement (equal movement of crown and root) |
| $M_C/M_F > 1$ | Torque (root apex moves further than crown) |

| Movement | M/F ratio | Center of rotation |
|----------------------|--------------|------------------------------------|
| Uncontrolled tipping | 0 | Apical of the center of resistance |
| Controlled tipping | -7 | Apex |
| Rotation (couple) | ∞ | Center of resistance |
| Translation | -10 | ∞ |
| Torque | -11.5 to -12 | Incisal |

- Moment to force ratio:

- *Definition Proffit:*
 - = The ratio between the moment created when a force is applied to the crown of a tooth (the moment of the force [MF]), and the counterbalancing moment generated by a couple within the bracket (the moment of the couple [MC]).
 - The moment of force is determined by the magnitude of force and the distance from the point of force application to the center of resistance.
 - $MF = h$
MF = Wieder-Aufrichtemoment geteilt durch die kippende Kraft.
 h = Hebelarm des Aufrichtemoments.
 - «Abstand zwischen Bracket und Angriffspunkt einer Einzelkraft, die die entsprechende Wirkung erzielen würde».
 - Clinical situation: MF = 8-10 mm for a tooth with a bracket:
100 gm net force needs a balancing moment of 800-1000 gm to obtain bodily movement. Adjustment necessary for:
 - Long roots
 - The amount of alveolar bone support (periodontal involved teeth)
 - Point of force application different than with usual conditions.

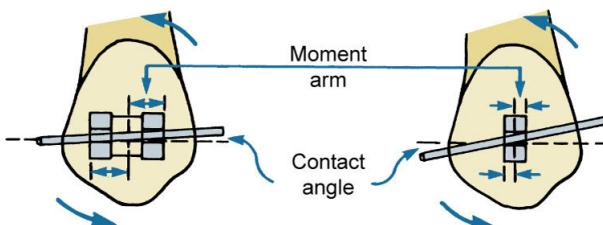

- Net force:

= force felt by a tooth. Important for tooth movement.

→ Resistance to sliding subtracted from the force applied to the brackets.

Drescher 1989:

The applied force must be x2 for ss wires and x6 for TMA wires to overcome friction.
For a couple created in a bracket, friction is rarely a factor.

|---|--|
| | <ul style="list-style-type: none"> - Clinic: Torque application needs time for expression and is proportional to bh^3. → Start early when torque is needed. |
| Root control with clear aligners | <ul style="list-style-type: none"> - Two-point contact for mesiodistal and buccolingual root movement is created with attachments. - The clinical effectiveness of these attachments is not clear. - Example: To provide a moment for lingual root movement on an upper incisor, a plastic ridge provides a lingual force on the facial surface near the gingival margin while a facial force is applied on the lingual surface near the incisal edge. |
| Bracket width | <ul style="list-style-type: none"> - Mesiodistal root movement is generated across the bracket in contrast to facial-lingual tooth movement which is created within the bracket. - Wider brackets (all other things being equal): <ul style="list-style-type: none"> Pro <ul style="list-style-type: none"> • Longer moment arm: Moment arm = half of the width of the bracket. → Less force is needed to create a moment → Easier to generate the moments needed to bring roots together at extraction sites / control mesiodistal position of roots. • Smaller contact angle: → Binding ↓ = advantageous for space closure by sliding. (Binding is affected by the force with which the bracket contacts the archwire and the contact angle between the wire and the bracket) Contra <ul style="list-style-type: none"> • Smaller inter-bracket space between adjacent teeth: → Shorter archwire length between supports: stiffness ↑, range ↓. - Maximum bracket width = half the width of a tooth. (extremely wide brackets are contraindicated)  <ul style="list-style-type: none"> - Narrow brackets: <ul style="list-style-type: none"> • Indicated for malaligned teeth: → The greater inter-bracket span increases the springiness of any wire. |
| Bracket slot size in the edgewise system | <ul style="list-style-type: none"> - 22 Slot: <ul style="list-style-type: none"> • Angle's original edgewise appliance = 22 x 28 mil bracket slot. <ul style="list-style-type: none"> ○ Designed for the use with gold archwires and narrow brackets. ○ Sliding was not important (non-ex concept), but application of torque. • Beneficial for sliding mechanics: <ul style="list-style-type: none"> ○ Minimum 2 mil clearance is necessary to minimize friction for sliding teeth along an archwire. More clearance is maybe even desirable. ○ → Use of undersized wires in edgewise brackets to minimize friction. ○ A 18 mil ss wire is more stable than a 16 mil ss wire. • Torque application is difficult: <ul style="list-style-type: none"> ○ Springiness and range are too small for a 21 mil wire. ○ Need of exaggerated inclination or torquing auxiliaries if smaller wires are used. ○ Difficulties can be overcome nowadays with the modern archwires. - 18 Slot: <ul style="list-style-type: none"> • Shift to 18 mil slots when brackets were redesigned for the use with ss wires instead of gold wires. • Good torque control. (forces slightly greater than in the original edgewise appliance) • Brackets must be bonded very precisely (little tolerance). • Smaller wires must be used → more vulnerable to mastication force etc. |
